INDEX.

NAME INDEX.

[illegible] eaching in Schools, 454
[illegible] elected secretary of the Smithsonian [illegible] ashington, 181
[illegible] .), [death], 66
[illegible] Stile), recommended for appointment [illegible] naval architecture at Armstrong [illegible]
[illegible] sorption of Ultra-sonic Waves by [illegible] Carbon Dioxide, 43
[illegible] ituary article], 594
[illegible] mination of the Colour-producing con- [illegible] Cacao Bean, 656
[illegible] n], 993
[illegible] .), presented with a Boyle medal of [illegible] n Society, 334
[illegible] O. Theodor, The Exit of *Leishmania* [illegible] he Proboscis of *Phlebotomus papatasii*, [illegible]
[illegible] Method of Alinement by Hertzian [illegible]
[illegible] y' Ultra-violet Lamp, 772
[illegible]), and others, The Control of Plant [illegible]
[illegible] dman), [death], 506
[illegible] Geology of the Highland Border from [illegible] anside, 889
[illegible] ermination of the Crystalline Network [illegible] ine Substances by means of Radio- [illegible] h Powders, 606
[illegible] e Circle and the Cross: a Study in [illegible] 2 Vols. Vol. 1: The Circle, 743
[illegible] nd Dr. A. L. Day, Steam Wells and [illegible] Activity at 'The Geysers,' California, [illegible]
[illegible]), Physics for Students, 237; The [illegible] Interpretation, 977; James Gregory, [illegible] ollins, and some Early Scientific Instruments, 456
[illegible] T. E.), and C. Sykes, The Alloys of Zirconium, 485
[illegible] G.), and Prof. R. V. Wheeler, The Pressures produced by Electric Arcs in Closed Vessels, 515
[illegible] ant (A.), and E. Rousseau, The Photolytic Action on Pure Saccharose of the Total or Filtered Radiations of the Mercury Arc, 442
Anderson (Anna I.), The Dielectric Constant of Liquid Bromine, 194
Anderson (D. B.), The Structure of Collenchyma Cell-wall deduced from Micro-chemical Investigations, 230
Anderson (Dr. J. A.), elected a member of the U.S. National Academy, 804
Andrade (Prof. E. N. da Costa), appointed Quain professor of physics at University College, London, 1038; Engines, 284
Andrews (H. I.), awarded a university post-graduate travelling studentship of London University, 1038
Andrews (Dr R. C.), resumption of work in the Mongolian Desert, 647
Angus (T. C.), Lamps for Light-Baths, 639
Anstruther-Gough-Calthorpe (Mr. and the Hon. Mrs.), gift to Birmingham University, 402
Antoniadi (M.), Observations of Mercury and the Jovian Satellites, 183
Antoniani (C.), The Influence of Superphosphate on the Reaction of the Soil, 229
Antonoff (Dr. G. N.), Experimental Measurement of the Surface Tension of Solids, 93
Appleton (Prof. E. V.), Variations of Radio Broadcasting Signals, 652; and J. A. Ratcliffe, On a Method of Determining the State of Polarity of Downcoming Wireless Waves, 193
Appleyard (R.), H. C. Oersted, 877; The Penzance Cable Station of the Western Union Telegraph Co., 767
Archey (G.), *Reference List* of the Scientific Periodicals in the Libraries of New Zealand, 509
Arciszewski (W.), and W. Kopaczewski, Microbial Antagonism and the problem of Cancer, 851
Armstrong (A. L.), M. C. Burkitt, H. Dewey, D. A. E. Garrod, and R. A. Smith, The Sligo Artefacts, 137
Armstrong (Dr. E. F.), elected a member of the Athenæum Club, 598
Armstrong (Prof. H. E.), Edward Frankland, 840; on Finsbury Technical College, 439; The Nature of Solutions, 48
Arnold (Sir Thomas), elected a member of the Athenæum Club, 725
Arnot (F. L.), The Interference of Light in a Wedge, 405
d'Arsonval, Bordas, and Besson, The Climatological Observatory of Mont-Revard, 486
Artom (C.), The Circulating Elements of the Hæmolymph of Euphyllopod Crustaceans, 306
Ashley (Sir William), The Bread of our Forefathers: an Inquiry in Economic History, 858
Ashmole (B.), appointed professor of archæology at University College, London, 402
Ashplant (H.), Yield Variability in *Hevea brasiliensis*, 1018
Ashworth (Dr. J. R.), The Relation of Specific Heat to Ferromagnetism, 323
Athanassopoulos (G.), The Limited Numbers of Young Eels ascending the Rivers in the Eastern part of the Mediterranean, 734
Atkins (Dr. W. R. G.), Lecture Experiments on the Hydrogen Ion Concentration Changes in the Rusting of Iron, 615; presented with a Boyle medal of the Royal Dublin Society, 334
Atkinson (R. d'E.), Statistical Experiments on the Motion of Electrons in Gases, 483
Aubert, Dumanois, and Pignot, The Effects of Antidetonants in the Vapour Phase, 926
Auld (Col. S. J. M.), Development of Natural Gas, 601
Ault (P. J.), Magnetic Ocean Surveys, 473
Auret (Theodora B.), The Reproduction and Fungal Endophytism of *Lunularia Cruciata* (L.) Dumortier, 890
Aveling (Dr F.), Directing Mental Energy, 162
Avram (M. H.), The Rayon Industry, 738

Babcock (H. D.), Photography of the Infra-red Solar Spectrum, 830
Badger (R. M.), The Pure Rotation Spectrum of Ammonia, 942
Baglioni (S.), Action of Quinine, Eserine, Pilocarpine, Digitonine, Sparteine, and Atropine on the Nervous Centres, 606; Physiological Doctrine of the Action of Poisons exciting the Nervous Centres, 606; and L. Settimj, The Nutritive Value of the Nitrogenous Substances of Certain Types of Preserved Foods, 406
Bailey (C. H.), The Reports of the Royal Commission on Mining Subsidence, 179

Bailey (C. R.), and K. H. Lih, Infra-red Emission of Carbon Dioxide, 941
Bailey (E. B.), Schist Geology: Braemar, Glen Clunie, and Glen Shee, 522
Bailey (G. L.), The Influence of Dissolved Gases on the Soundness of 70 : 30 Brass Ingots, 484; The Influence of Gases on the Soundness of Brass Ingots, 809
Baird (A. H.), A New Device for Reading Burettes, 884
Baird (J. L.), The Transmission of Living Pictures to New York, 255
Baird (T.), [obituary article], 107
Baird and Tatlock (London), Ltd., Standard Catalogue of Scientific Apparatus. Vol. 1, Chemistry. New edition, 112
Baker (C.), Catalogue of Second-hand Scientific Instruments, 918
Baker (E. A.), The Law of Blackening of the Photographic Plate at Low Densities (3), 805
Baker (Prof. H. B.), Constitution of Liquids: Some New Experiments, 507
Baker (Prof. H. F.), Note on the Paper, "Commutative Ordinary Differential Operators," by J. L. Burchnell and T. W. Chaundy, 304
Baker (T. Thorne), Microscope Technique, 299
Baker (T. Y.), The Design of Reflecting Prisms, 41
Baker (W. C.), Experiments with Mercury Jets and the Phenomena exhibited at their Impact with Steel and Glass, 814
Balasse (G.), The Continuous Emission Spectrum produced by the Electrodeless Discharge, 405
Balavoine (P.), A Seasonal Variation of the Composition of Butter Fat, 122; The Tannin Content of Wine is Influenced by the Climatic Conditions at the Time of Vinification, 927
Baldet (F.), The Spectra of Comets, 550
Baldwin (Dr. B. T.), [death], 993
Ball (W. W. Rouse), Histoire des mathématiques. Édition française revue et augmentée, traduite sur la troisième édition anglaise par Lieut. L. Freund. Tome 1, 932
Ballantyne (Miss F. M.), Air Bladder of Fishes, 34
Baly (Prof. E. C. C.), Photosynthesis, 218
Bancroft (B. B.), On the Notational Representation of the Rib-System in Orthaceae, 442
Barbarin (Prof. P.), La géométrie non euclidienne. Trois. édition, par A. Buhl, 584
Barclay (Dr. A. E.), appointed lecturer in medical radiology and electrology in Cambridge University, 924
Bardet (J.), and A. Tchakirian, The Preparation and Properties of some Germanous Salts, 606
Barfield (R. H.), Woods and Wireless, 908
Barker (J. Ellis), Good Health and Happiness: a New Science of Health, 369
Barker (Dr. T. V.), appointed secretary to the curators of the Oxford University Chest, 342
Barley (A. H.), The Ice Age, 395
Barnard (J. E.), elected president of the Royal Microscopical Society, 146
Barnes (C. L.), Milton and Modern Science, 831
Barrett (C. S.), The Scattering of X-rays from Gases, 658
Barrett (W. H.), Chemistry, 495
Barrien and Nemours-Auguste, The Technique and the Results of the Treatment of Angina Pectoris by Radiotherapy, 523
Barry (H.), Malay Resins and the Trade, 653
Bartlett (F. C.), Psychology and the Soldier, 89
Bartlett (Capt. R. A.), to lead an expedition to Nicholas Land, 256
Bassett-Smith (Surg. Rear-Adml. Sir Percy), [death], 28
Bates (Dr. F.), The Specific Heats of Ferromagnetic Substances, 192
Bates (J. R.), and D. H. Andrews, Fundamental Frequencies, Interatomic Forces, and Molecular Properties, 735
Bath (Dr. F.), appointed lecturer in mathematics in St. Andrews University, 775
Bather (Dr. F. A.), elected a corresponding member of the Geological Society of Stockholm, 181; elected president of the Palaeontographical Society, 724; European Echinoderms, 52; The Hungarian Biological Research Institute, 93[illegible]
Baudouin (M.), and Morel, A Unique Case of Palaeopathology, 778
Baumann (J.), [obituary], 28
Baxandall (F. E.), reappointed a senior observer at the Solar Physics Observatory, Cambridge, 775
Baxter (G. P.), and H. W. Starkweather, The Density, Compressibility, and Atomic Weight of Neon. The Density, Compressibility, and Atomic Weight of Argon, 659
Bayle (E.), H. George, and A. Mache, The [illegible]ification of Works of Art, 158
Beams (Dr. J. W.), Mechanical P[illegible] Short Flashes of Light, 863
Beck, Ltd. (R. and J.), A Patholog[illegible] 845; Order to, for Microscopes for [illegible]d of Hygiene and Tropical Medicine, 596[illegible]
Beckinsale (S.), and H. Waterhouse, The [illegible]ad Cable Sheathing, 441, 922
Beebe (R. A.), and D. B. Summers, [illegible]er Sulphate in the Deacon Process, 601 [illegible]
Beers (C. D.), Some Effects of Dietary [illegible] Ciliate *Didinium nasutum*, 735
Belfort (R.), Cable-radio Operations, 54[illegible]
Bell (G. E.), A Valve-maintained [illegible]duction Furnace, etc., 814
Bell Telephone Co., a New Loud Speake[illegible]
Belling (Dr. J.), A Working Hypothes[illegible] Interchange between Homologous Ch[illegible] Genes and Chromomeres in Flowe[illegible] Segmental Interchange and Crossing[illegible]
Bellingham and Stanley, Ltd., An Ultra-[illegible] New Electrodes, 688
Belot (E.), The Seismicity of the Sun [illegible] of Magnetic Storms, 42
Bénard (H.), Vortices in Bands and Ra[illegible]
Benedetti (E.), Certain Modifications [illegible] Alcoholic Fermentation due to [illegible] Oscillating Electromagnetic Field [illegible] 229
Benham (Prof. W. B.), Polychaeta [illegible] (Natural History). British Antar[illegible] Expedition, 1910. Natural History, [illegible] Vol. 7, No. 2), 856
Bennett (A. R.), [death], 914
Bennett (E. N.), Apollonius: or The [illegible] of Psychical Research, 569
Bennett (E. W.), Fission in Starfishes, [illegible]
Bennett (H. H.), and R. V. Allison. Th[illegible]
Bennett (M.), The Dalleburra Tribe, [illegible] 686
Bennett and Mardles, Ionisation and [illegible] during Slow Combustion, 259
Bent (A. C.), North American Shore Birds, [illegible]
Bernard (Claude), Translated by H. C. [illegible] Introduction to the Study of Experiment[illegible] 387
Bersa (E.), Actino-biological Researches, 230
Bert (L.), A New General Synthetic Method for Pre[illegible] Arylaliphatic Aldehydes, 657; Houben's reac[illegible] 559; The Synthesis of Benzene Hydrocarbons [illegible] Means of Mixed Organomagnesium Compounds, 442
Bertram (B.), Mosquito Control in the Municipality of Lane Cove, N.S.W., 266
Bertrand (G.), and G. Nitzberg, the Ketonic Function of α-Glucoheptulose, 889; The Preparation, by the Sorbose Bacterium, of a New Reducing Sugar containing Seven Atoms of Carbon, 777; and J. Labarre, The Acetolysis of Mannocellulose, 158; and L. Silberstein, The Ordinary Presence of Barium, and probably of Strontium, in Arable Earth, 442; The Properties of Barium contained in Arable Soil, 523; and Mme. M. Rosenblatt, The General Presence of Sodium in Plants, 345
Besredka (Prof. A.), edited and translated by Dr. H. Plotz, Local Immunization: Specific Dressings, 382
Besson (L.), The Visibility and Amount of Dust in the Air of Paris, 734
Best (C. H.), and Ruth Partridge, The Equation of Motion of a Runner exerting a Maximal Effort, 1005
Bethune-Baker (Rev. J. F.), The Way of Modernism: and other Essays, 290

Bezssonoff (N.), The Immediate Physiological Action of a Vitamin, 734
Bickerton (W.), The Baby Bird and its Problems, 383
Bickley (W. G.), The Distribution of Stress round a Circular Hole in a Plate, 970; The Influence of Vortices upon the Resistance experienced by Solids moving through a Liquid, 969
Bierry (H.), and M. Kollmann, The Mode of Action of Vitamin B, 851
Biggs (H. F.), Recent Progress in Theoretical Physics, 503
Bigourdan (G.), The Various Methods used for the Calculation of Pendulum Corrections, 926
Bilancini (R.), The Anemological Regime of the Gulf of Spezia, 779
Biles (H. J. R.), awarded a premium by the Institution of Naval Architects, 334
Bills (Dr. C. E.), and F. G. Brickwedde, The Activation of Cholesterol at Liquid Oxygen Temperature, 452
Billy (M.), The Composition of Titanium Peroxide, 694
Binet (L.), and R. Fabre, Variations of the Amount of Uric Acid in the Blood according to the State of the Respiratory Function: Hyperuricaemia due to Asphyxia, 778
Birge (Prof. R. T.), The Hydrogen Molecule, 134
Birmingham Electric Furnaces, Ltd., Electric Furnaces in Metallurgy, 728
Bjerknes (Prof. V.), World Meteorology, 931
Black (J. W.), and B. J. W. Warren, Notes on the Effect of Other Reducing Substances on the Determination of SO_2, 265
Blackman (Winifred S.), The Fellāhīn of Upper Egypt: Their Religious, Social, and Industrial Life To-day, with Special Reference to Survivals from Ancient Times, 380
Blagg (Miss M. A.), Oscillations in the Period of Beta Lyrae, 512
Blaikie (Dr. W. B.), [obituary article], 801
Blakely (W. F.), The Loranthaceae of Australia. Part 7, 1044
Bledisloe (Lord), the new post of, 178
Bles (Dr. J. E.), the bequests of, to Cambridge University, 481
Bloch (E.), translated by J. R. Clarke, Thermionic Phenomena, 162
Bloch (O. F.), The Chemist in the Photographic Industry (Streatfeild Memorial Lecture), 474
Blondel (A.), The Adaptation of Bifilar Oscillographs to the Study of Triode Waves, 850
Bloomer (H. H.), Form Variations of the British Freshwater Pearl Mussel, 552
Blum (L.), and P. Grabar, The Alterations in the Renal Function by Hypochlorination, 306
Blunck (G.), Photography of the Corona without an Eclipse, 183
Blyth (J. S. S.), The Relation of Gonadic Structure to Comb Growth in the Fowl, 485
Bobrovnikoff (N. T.), Cometary Spectra, 769; Comets, 881; The Spectra of Comets, 550
Bodine (J. H.), The Action of Na, K, and Ca Chlorides on the Egg of Fundulus, 42
Bodroux (D.), The Condensation of Cyclohexene with some Aromatic Hydrocarbons in the Presence of Aluminium Chloride, 814
Bogert (Prof. M. T.), awarded the Charles' University medal; conferment upon, of an honorary doctorate by the Charles' University, [illegible]47
Bogitch (B.), Some Properties of Electrolytic Nickel, 158
Bohr (Prof. N.), The Quantum Postulate and the Recent Development of Atomic Theory, 78, 580
Boltwood (Prof. B. B.), [obituary article], 64
Bonacini (Prof. C.), The Photographic Detection of Falsified Documents, 223
Bond (Dr. C. J.), The Distribution of Natural Capacity in the Population and the Need for a National Stocktaking (Galton Lecture), 291
Bone (Prof. W. A.), D. M. Newitt, and C. M. Smith, Gaseous Combustion at High Pressures. Part 9, 193
Bonnerjea (Dr. B.), Magic and Taboo in Bengal, 1033
Bonser (W.), Prices of Periodical Scientific Publications, 538
Boone (L.), Some Tropical Crustacea, 1033
Bornstein (Prof. E.), The Constituents of Low-Temperature Tar, 356
Bose (Prof. D. M.), Magnetic Theory, 477
Bose (Dr. E.), [death], 142
Bose (Sir Jagadis Chunder), Collected Physical Papers, 451; Lectures in Vienna, 994; elected a foreign member of the Vienna Academy of Sciences, 995
Bosmans (H.), [death], 801
Boss (A. E.), and B. S. Hopkins, The Purification and Atomic Weight of Erbium, 728
Boss (Dr. B.), The Recent Transit of Mercury, 550
Boswell (Prof. P. G. H.), Geological Features of the New Mersey Tunnel, 970; Geology of the Alps, 412
Bothe (W.), and H. Fränz, Artificial Disintegration of Elements, 651
Boule (Prof. M.), et L. de Villeneuve, La Grote de l'Observatoire à Monaco, 1012
Bourcet (P.), and G. Dugue, The Digitin of Nativelle, 443
Boutaric (A.), and F. Ba[illegible]a, The Immunity of the Granule in Colloidal Solutions, 814; and Mlle. G. Perreau, The Determination of Dilute Saline Solutions by the Opacity of Fine Suspensions obtained starting with These Solutions, 657
Bowen (Prof. I. S.), The Life of Atomic States and the Intensity of Spectral Lines, [illegible]58
Bower (Prof. F. O.), The Size-factor in Plant Morphology, with Special Reference to the Stele, 777
Bowie (Dr. W.), First-order Triangulation in the United States, 115
Boyer (C.), North American Diatoms, 148
Boyer (C. S.), [death], 956
Boyle (Dr. R. W.), Transmission of Sonic and Ultrasonic Waves through Partitions, 55
Boys (Prof. C. V.), Solid Dipleidoscope Prisms, 1040
Bracewell (S.), Geology of British Guiana, 514
Brachet (Prof. A. T. J.), elected a foreign member of the Royal Society, 1036
Bradford (Sir John Rose), William Harvey, 768
Bragg (Sir William), From Faraday's Note-books; 218, 254, 293; přeložili Prof. A. Šimek a Dr. Hannah Šimoková-Kadlcová, O povaze věcí, 495; Prof. H. A. Lorentz, 287; The Enhancement Principle in X-ray Photographs, 327; The Structure of an Organic Crystal (Fison Memorial Lecture), 471
Brambell (Dr. F. W. R.), Development and Morphology of the Gonads of the Mouse. Part 2, 157
von Branca (Prof. W.), [death], 624; [obituary article], 801
Brasch (A.), F. Lange, and C. Urban, Thunderstorms as Sources of High Potentials, 552
Brauner (Prof. B.), Prof. J. V. Danes, 874; What Becomes of Stellar Radiation? 674
Braunholtz (H. J.), An Ancestral Figure from New Ireland, 33
Bray (F.), Light, 237
Breasted (Prof. J. H.), Work of the Oriental Institute of the University of Chicago, 682
Brecher (Dr. L.), elected Yarrow research fellow at Girton College, 481
Breder, Jr. (C. M.), New Deep Sea Fishes, 297
Breit (G.), and M. A. Tuve, The Production and Application of High Voltages in the Laboratory, 535
Bresadola (Abbé G.), elected a corresponding member of the Botanical Society of America, 255
Breuil (H.), et le Comte R. de Saint-Périer, Les Poissons, les Batraciens et les Reptiles dans l'art quaternaire, 1012
Briant (T. J.), Eyeglasses and the Microscope, 209

TITLE INDEX.

α-bromaldehydes, The Reactions of the, A. Kirrmann, 158
α-diketones, The Tautomerism of the, H. Moureu, 523
Aberdeen University, Prof. J. J. R. MacLeod appointed professor of physiology, 654; Lord Meston elected Chancellor, 731
Abetti, Prof. A., and the 1874 Transit of Venus, W. A. Parr. 675
Absorption Photometer, A Critical, for the Study of the Compton Effect, Prof. C. V. Raman and C. M. Sogani, 969
Abyssinian Augitite, An, L. Duparc and E. Molly, 78
Acid Anhydrides, The Decomposition of, J. Campardou and M. Séon. 559
Acoustics of Buildings, The, Dr. A. H. Davis and Dr. G. W. C. Kaye; Dr. W. H. George, 611
Actino-biological Researches, E. Bersa, 230
Activated Sludge: Process, The, A. J. Martin, 165; Study of, L. Cavel, 486
Adelaide University, Dr. A. K. Macbeth appointed Angas professor of chemistry. 120; award of the degree of D.Sc. to Dr. A. W. Hill, 219; Waite Agricultural Research Institute, Dr. J. Davidson appointed head of the Department of Entomology at, 1038
Aden, Gulf of, Temperature and Salinity Observations in the, D. J. Matthews, 92
Adhesion, Studies in (3), M. Nottage, 483
Adventure: the Faith of Science and the Science of Faith, Rev. Canon B. H. Streeter, Catherine M. Chilcott, J. MacMurray, and Dr. A. S. Russell, 448
Aerial: Circuit, A Tuned, 472; Surveying, A New Method of (2), H. G. Fourcade, 42
Aerofoil, the Lift of an, The Effect of Compressibility on, H. Glauert, 193
Aeronautic Structure, The Weight of the, G. A. Crocco, 1043
Aeroplane Flight to Australia, Record, by B. Hinkler; Sir Samuel Hoare, 332
Aeroplanes: Control of, Research on the, Prof. B. Melvill Jones, 755, 765, 940: Lt.-Col. W. L. Marsh, 939; Longitudinal Stability in, S. B. Gates, 965
Africa, No. 1. 294
Africa: South Central, The Forest Flora of, P. J. Greenway, 558; The Rocks of, W. Campbell Smith, 1034
African: Elephant, The Anatomy of a Fœtal, Part 2, N. B. Eales. 41; Religions, Dualism in, G. W. B. Huntingford, 599
Agathosma Microphylla, The Essential Oil of, J. L. B. Smith and K. A. C. Elliott, 890
Agglutination, Phenomena of, The Influence of Some Electrolytes on the, M. Pieттre and A. Chrétien, 42
Agriculture, Scientific, The Application of, 1009
Agricultural: Depression, The, Its Causes and Possible Cures, W. C. Dampier-Whetham, 646: *Progress*, 1009; Research: Imperial, 781; in Connecticut, 687
Air: Bladder of Fishes, Miss F. M. Ballantyne, 34; Conditioning in Industry, N. E. Jackson, 753; of the Streets of Paris, The Composition of the, D. Florentin, 159; -resistance to a Runner, The, Prof. A. V. Hill, 228; Survey, The Stereoscope in, Lieut. M. Hotine, 259; Tragedies, Sir Samuel Hoare, 804
Albino Rat, The Daily Thermal Curve of the, A. Galamini, 306
Albumens, The Antigen Character of, modified by Heating and Their Specific Differentiation by Precipitating Sera, E. Nicolas and K. Katrandjieff, 851
Alcohol, New Data on, and Duration of Life, Prof. R. Pearl and Agnes Latimer Bacon, 15
Alcoholic, Fermentation, Certain Modifications in the Course of, due to the Action of the Oscillating Electromagnetic Field on the Yeast (2), E. Benedetti, 229; Hydrochloric Acid, Action of, on Methyldiphenyltetrahydropyrone, Prof. H. Ryan and J. J. Lennon, 1042
Alcohols: and Salts, The Equilibrium between, E. Lloyd, C. Brown, D. Bonnell, and W. J. Jones, 884; into Petrol, The Transformation of, A. Mailhe and Renaudie, 194
Alcyonaria of the Abrolhos Islands, Mrs. L. Hunter, 441
Algæ of a Bog: The, Five Years' Observations, A. M. Smith, 484
Alinement, A New Method of, by Hertzian Waves, J. Ascardi, 405
Alkali: and Halogen Atoms, The Non-appearance of the Recombination Luminescence in the Reaction between, V. Kondratjew, 571; Metals, Band Fluorescence of, The Atomic Spectral Lines Associated with the, Prof. J. C. McLennan and R. Ruedy, 500
Alkaline Earth Halide Spectra, The, and their Origin, O. H. Walters and S. Barratt, 304
Allen's Commercial Organic Analysis. Vol. 5. Fifth edition. Editors: S. S. Sadtler, Dr. E. C. Lathrop, C. A. Mitchell, 613
Alloys: Cast, of Heterogeneous Structure, Minute Shrinkage Cavities in Some, W. A. Cowan, 442; Hardness of, A. Mallock, 827; The Microstructure of, Dr. W. Rosenhain, 441
Alpen, Die Deckentheorie in den (Alpine Tektonik, 1905-1925), Prof. F. Heritsch, 412
Alpine Cloud Forms, Some, C. K. M. Douglas, 733
Alps: Divisions of the, D. W. Freshfield, 222: Geology of the, Prof. P. G. H. Boswell, 412; The Structure of the, Prof. L. W. Collet, 412
Aluminium: Alloys and Bronzes, The Thermal and Electrical Conductivity of Some, Dr. Ezer Griffiths and F. H. Schofield, 441; Extra-pure, The Action of Hydrochloric Acid upon, J. Calvet, 442; in its Salicylate Derivatives, The Co-ordination Valency of, G. J. Burrows and I. W. Wark, 553: The Magnetic Susceptibility of, C. Chéneveau, 851
America, The Early Races of, Dr. E. B. Renaud, 257
American: Academy of Arts and Sciences, Prof. D'Arcy W. Thompson elected a foreign honorary member of the, 879; Association, award of the prize of the, to Prof. H. J. Muller, 146; Prof. H. F. Osborn elected president of the, 146; Astronomical Society, Dr. Max Wolf elected an honorary member of the, 111; Game Shooting, Capt. P. A. Curtis, 277; Geophysical Union, the eighth annual meeting of the, 598; Institute of Chemical Engineers, Dr. E. R. Weidlein re-elected president of the, 111; Magpies, Carnivorous Habit of, E. R. Kalmbach, 336
Amerindian Crosses in Canada, A Pedigree Study of, Prof. R. R. Gates, 265
Amino-acids in Insects, The Presence of Large Quantities of, M. Duval, P. Portier, and Mlle. A. Courtois, 606
Aminosulphonic Acid, Action of, on Unsaturated Compounds, A. Quilico, 695
Ammonia: A Heterogeneous Thermal Decomposition of, in Strong Electric Fields, R. E. Burk, 43; Sodium, and Calcium Phosphates, etc., Behaviour of Indicators in the Titration of, R. T. Thompson, 521; The Formation of. by the Silent Electric Discharge in the Presence of Mercury, A. Van der Wijk. 122; The Formation of, in the Preparation of Phosphorus, E. Urbain and V. Henri, 889; The Pure Rotation Spectrum of, R. M. Badger, 942; The Synthesis of, by Alpha Rays, S. C. Lind and D. C. Bardwell, 884
Ammonium and Phosphonium Halides, Isomorphism of, Congilio and Cagliotti, 553
Analcite-syenites and Associated Rocks of Ayrshire, The, Dr. G. W. Tyrrell, 693
Analysis: Modern, A Course of, An Introduction to the General Theory of Infinite Processes and of Analytic Functions; with an Account of the Principal Transcendental Functions, Prof. E. T. Whittaker and Prof. G. N. Watson. Fourth edition, 417
Analysts, Public, Society of, election of officers, 432
Anatomy, Recent Advances in, Prof. H. Woollard, 385

Ancestral Figure from New Ireland, An, H. J. Braunholtz, 33

Ancient: Civilisations; from the Earliest Times to the Birth of Christ, D. A. Mackenzie, 567; Weights and Measures: Illustrated by the Egyptian Collection in University College, London, Sir Flinders Petrie, 311

Ancylostoma, The Species of, B. Schwartz, 184

Angina Pectoris, The Technique and the Results of the Treatment of, by Radiotherapy, Barrieu and Nemours-Auguste, 523

Angler-Fishes, Oceanic, post cards of, 257

Aniline, On the Measurement of the Specific Heat of, with Temperature, using the Continuous-flow Electric Method, H. R. Lang, 193

Animal: Biology, J. B. S. Haldane and Prof. J. S. Huxley, 371; Ecology: with Especial Reference to Insects, R. N. Chapman. Second edition, 274

Annual Register: The, 1927, edited by Dr. M. Epstein, 902

Antarctic: Projected Expedition by Comdr. R. E. Byrd to the, 146; Waters, L. Christensen and Research in, 219

Anthrax, Vaccination against, E. Leclainche and H. Vallée, 305

Anthraxolite of Sudbury, The, Prof. A. P. Coleman, 337

Anthropological Research in Australia, 1001

Anthropology, The Value of, J. H. Hutton, 645

Anthropometric Measurements and School Progress, Dr. A. A. Mumford, 38

Antidetonants: The Theory of, P. Dumanois, 405; in the Vapour Phase, The Effects of, Aubert Dumanois, and Pignot, 926

Anti-Malarial Measures in Europe, 75

Antimony: Colorimetric Determination of Small Quantities of, and their Separation from Tin, S. G. Clarke, 656; from Different Sources, The Atomic Weight of, K. R. Krishnaswami, 73

Antirachitic Vitamin D, Bird Feathers and the, Prof. W. Rowan, 323

Antiseptic Solution, A New, 652

Antlers carried by Female Deer, J. Dixon, 807

Ants: The Social World of the, compared with that of Man, Dr. A. Forel. Translated by C. K. Ogden. 2 Vols., 819; The Societies of, Prof. J. S. Huxley, 819

Apollonius: or the Present and Future of Psychical Research, E. N. Bennett, 569

Aquaria, Aeration of, Prof. H. G. Cannon and Dr. A. J. Grove, 184

Aquarist and Pond Keeper, the new name of the *Amateur Aquarist and Reptilian Review*, 256

Aqueous-alcoholic Mixtures, The Dielectric Properties of, P. Brun and J. Granier, 266

Arabia: South-eastern, G. M. Lees, 115, 229

Archæological Discoveries by Aeroplane at Dorchester, O. G. S. Crawford, 71

Archimedes: or the Future of Physics, L. L. Whyte, 534

Arctic: Aviation, 853; Aeroplane Flight, Capt. G. H. Wilkins and C. B. Eielson, 681, 722; Ice in 1927, 600

Argentine Rock-Paintings, G. A. Gardner, 184

Argon: (A II), Ionised, The Spectrum of, Dr. T. L. de Bruin, 576; The Density, Compressibility, and Atomic Weight of, G. P. Baxter, and H. W. Starkweather, 659

Armstrong College, resignation of Prof. J. J. Welch; Prof. T. H. Havelock appointed professor of applied mathematics, and director of the department; Dr. G. R. Goldsbrough appointed professor of mathematics, 402; the Gilchrist Memorial, 481

Aromatic Amines, Action of, on Nitric Esters, Prof. H. Ryan and M. T. Casey, 1042

Arrhenius Memorial Lecture, The, Sir James Walker, 803

Artificial Sunlight: Apparatus for, Watson and Sons (Electro-Medical), Ltd., 1035; in Private Houses, Medical Aspects of, Dr. P. B. Peacock, 638

Art, Works of, The Identification of, R. Boyle, H. George, and A. Mache, 158

Arunta: The, A Study of a Stone Age People, Sir Baldwin Spencer and the late F. J. Gillen. 2 Vols., 411

Arylaliphatic Aldehydes, A New General Synthetic Method for preparing, L. Bert, 657

Ash Pictures of technically useful Barks, K. Czapla, 523

Asia, Central, Zoological Studies of, M. Ivanova-Berg, 396

Aspergillus niger, The Formation of Citric Acid by, Dr. F. Challenger, L. Klein, V. Subramaniam, and Dr. T. K. Walker, 244

Association of Teachers in Technical Schools. Conference at Bradford, 967

Astigmatism, The Correction of, Dr. T. J. I'a. Bromwich, 747

Aston Dark Space, The, Dr. K. G. Emeléus and Miss N. M. Carmichael, 14

Astronomical Discovery, W. F. Denning, 1032

ASTRONOMICAL NOTES.

Comets:
  Comets, 32; The Recent Great Comet, 113; Skjellerup's Comet, 147; New Comet, 235; Comets, 395, 433; Skjellerup's Comet, 475; Comets, 512; The Spectra of Comets, N. T. Bobrovnikoff; F. Baldet, 550; Comets, 649; Cometary Spectra, N. T. Bobrovnikoff, 769; Comets, 806; Comets, N. T. Bobrovnikoff, 881

Instruments:
  Photographic Stellar Photometry at Allegheny, 147

Meteors:
  Large Meteor on Jan. 9, 113; Bright Meteors, W. F. Denning, 147; Bright Meteor on Feb. 3, W. F. Denning, 220; April Shower of Meteors, 649; Meteor Showers of April and early May, W. F. Denning, 725; Bright Meteor from Halley's Comet, 769; A Probable Meteoric Display, I. Yamamoto, 881; Meteors and Skjellerup's Comet, W. F. Denning, 997

Observatories:
  Annual Report of University Observatory, Oxford, 475
  The Ebro Observatory, 685

Planets:
  Observations of Mercury and the Jovian Satellites, M. Antoniadi, 183; Preparations for the Near Approach of Eros in 1931, 475; The Recent Transit of Mercury, Dr. B. Boss, 550; Search for a Planet outside Neptune, Prof. W. H. Pickering, 598; The Planet Mercury, W. F. Denning, 842; Planetary Photography, Prof. W. H. Wright, 962; Discovery of Minor Planets, 962; Colour Photography of the Moon, F. J. Hargreaves, 997; Conjunction of Mars and Jupiter, 1032; Variation in the Earth's Rotation, Prof. de Sitter, 1032

Stars:
  Parallaxes of Binary Stars deduced from Assumptions of their Mass, R. O. Redman, 183; Has Sirius changed Colour? Prof. T. J. J. See; E. Dittrich, 296; Analysis of Cepheid Variables, W. Zessewitsch, 296; Nova Pictoris, 433; Oscillations in the Period of Beta Lyræ, Miss M. A. Blagg, 512; Stellar Parallaxes from Allegheny Observatory, 550; Stereoscopic Parallaxes of 125 *B*-type Stars, D. L. Edwards, 598; Minimum of ε Aurigæ, Miss Cecilia H. Payne, 598; Nova Pictoris, 649, 685; ε Aurigæ, 685; The Structure of the Galactic System, Dr. Seares, 725; Nova Pictoris, 806; A Suggested Cause of New Stars, M. C. Johnson, 842; The System of Procyon, Dr. Spencer Jones, 881; Nova Pictoris, Dr. H. Spencer Jones, 962; The Distances of the Spiral Nebulæ, R. Hess, 997

Sun:
  Recent Solar Activity, Newbegin, 220; The Total Eclipse of Aug. 31, 1932, 256; The Sun's Rotation and the Relativity Shift of Spectral Lines, J. Evershed, 256; A Large Sunspot, 335; Recent Solar Activity, 806

Miscellaneous:
  Recent Display of the Aurora Borealis, C. Leaf, 32; The Ancient Astronomy of the Mayas, Dr. H. J. Spinden, 147; Photography of the Corona without an Eclipse, G. Blunck, 183; Another Test of the Einstein Bending of Light, 220; Fixing the Date of Easter, 256; Periodic Variations in Terrestrial Magnetism, K. F. Wasserfall, 296; The Gregorian Calendar in Egypt, 335; The Drayson Paradox, 395; Extent and Duration of the Universe, Dr. J. H. Jeans, 433; The Einstein Deflexion of Light in the Eclipse of

Sept. 1922, Prof. W. W. Campbell and R. J. Trumpler, 769; Magnetic Storms and Sunspots, 842; The Fixing of Easter,' 1032; Astronomical Discovery, W. F. Denning, 1032

Astronomy, Field, A Manual of, Prof. A. H. Holt. Second edition, 860

Asymmetrical Optical Systems, Canonical Forms in the Theory of, T. Smith, 305

Athenæum Club, election of: W. L. Hichens, 394; Dr. E. F. Armstrong, Dr. J. B. McEwen, and Prof. R. W. Seton Watson, 598; Sir Thomas Arnold, Principal W. R. Halliday, and Prof. A. G. Tansley, 725

Atmospheric Corrosion of Metals, The Application of Electrical Resistance Measurements to the Study of the, J. C. Hudson, 404

Atom: Certain Properties of the, Statistical Deduction of, E. Fermi, 1043; Determination of Certain Properties of the, A Statistical Method for the (1), E. Fermi, 607; Mechanics of the, The New Outlook on the, Prof. C. G. Darwin, 41

Atomic: States, The Life of, and the Intensity of Spectral Lines, Prof. I. S. Bowen, 658; Streams on Surfaces, On Phenomena occurring in the Condensation of, J. D. Cockcroft, 970; Volume Relations in Certain Isomorphous Series (2), On the, A. F. Hallimond, 656

Atoms: of Radioelements, The Phenomenon of Grouping of, Mlle. C. Chamie, 42; Structure of, A Periodic Table of the, and its Relations to Iron Formation and Valence, Prof A. A. Noyes and A. O. Beckman, 230

Aurora Borealis, Recent Display of the, C. Leaf, 32

Auroræ accompanied by Noises? Are, 398

Auroral Green Line, Excitation of the, in Active Nitrogen, J. Kaplan, 711

Australia: A Geophysical Survey of Parts of, 462; Anthropological Research in, 1001; Power Alcohol in, Prof. J. Read, 175; Precarboniferous Plants from, Prof. W. H. Lang and Miss Isabel Cookson, 477; Research and Development in, 427; The Loranthaceæ of, W. F. Blakely (7), 1044; The Proposed Central Scientific Station for Problems of the Sheep Industry, 721

Australian: Araucarian Conifers, The Growth-rings in Wood of, W. D. Francis, 1044; Coleoptera, Notes on, with Descriptions of New Species, C. G. Oke (1), 1043; Commonwealth Council for Scientific and Industrial Research, establishment of an entomological section under Dr. R. J. Tillyard, 30; Flora, Origin and Development of Portion of the, R. H. Cambage, 554; Government Palæontologist, F. Chapman loaned as, 31; Marine Algæ, Notes on, No. 5, A. H. S. Lucas, 266

Austria, Geological Survey of, Mrs. Ogilvie Gordon nominated an honorary correspondent of the, 996

Autogyro, Theory of the, H. Glauert, 921

Automobile Engineers, Institution of, award of the Institution's medal to Major G. S. Wilkinson, 648

Autoxidation and Antioxygen Action, C. Moureu and C. Dufraisse, 194, 345

Auxiliary Chronometer *Nm* of the Observatory of Geneva, The, and the Rating of Chronometers submitted for Examination, P. Rossier and G. Tiercy, 927

Avicennæ de Congelatione et Conglutinatione Lapidum: being sections of the Kitâb Al-Shifâ. Edited with an English translation and with Critical Notes by E. J. Holmyard and D. C. Mandeville, 387

Avokaiya Fishing, E. E. Evans-Pritchard, 551

Azomethane, The Theory of the Decomposition of, O. K. Rice, 735

β-rays, The Dependence of the Photographic Action of, on their Velocity, C. D. Ellis and G. H. Aston, 970

Babylonian Artificial Lapis Lazuli, Prof. Neumann, 186

Bacterial Proteins: Presence of Alcohol-soluble Proteins in Bacteria, Sir Kenneth Goadby, 157

Bacteriological Equivalents: Dictionary of, French-English, German-English, Italian-English, Spanish-English, W. Partridge, 9

Bacteriology: Laboratory Technique in, An Introduction to, Dr. M. Levine, 132; Practical, The Principles of, for Scientific Workers, J. H. Johnston and Dr. R. H. Simpson, 132

Baird and Tatlock (London), Ltd., Standard Catalogue of Scientific Apparatus, Vol. 1 (chemistry), new edition, 112

Baking Ovens, The use of Electricity for, E. Styles, 181

Bamboo, Periodical Flowering of, Seiichi Kawamura, 435

Banisterine, extracted from *Banisteria Caapi*, L. Lewin, 486

Barium: contained in Arable Soil, The Proportions of, G. Bertrand and L. Silberstein, 523; Sulphate Losses in Gravimetric Estimations, H. R. Jensen, 265; The Ordinary Presence of, and Probably of Strontium, in Arable Earth, G. Bertrand and L. Silberstein, 142

Barley Varieties, Differential Response of, to Manuring, F. G. Gregory and F. Crowther, 136

Barrages: Triangular, The Thickness required in, A. Mesnager, 733; with Overflow Weir, The Technique of Reduced Models of, L. Escande, 229

Basal Metabolism in Health and Disease, Prof. E. F. Du Bois. Second edition, 314

Base Exchange: and the Formation of Coal, Dr. E. McKenzie Taylor, 789; and the Formation of Petroleum, Dr. M. Stuart, 940

Basic Science, The, 823

Batteries with Unalterable Electrodes and Carnot's Principle, V. Karpen, 345

Battersea Polytechnic: Exhibition at, 519; Report for 1926–27, 76

'Bauxite' from Kashmir, India, T. V. M. Rao, 656

Bayliss and Starling, Proposed Studentship at University College in Memory of, 594

Beam from a Standard Lighthouse Lens, The, W. M. Hampton, 483

Beats by High-frequency Interruption of Light, Prof. S. K. Mitra and D. Banerji, 573

Bee Mite, Infection and Immunity in the, 822

Beetles Injurious to Timber, Dr. J. W. Munro, 221

Behave: How we, an Introduction to Psychology, Prof. A. E. Heath, 88

Beisan, A. Rowe, 919

Belgian: Forests, Quaternary History of, Vestiges of the Recent, G. Erdtmann, 734

Belgium: Royal Academy of, elections to the, 31; scientific work in, 722; prize awards of the, 879

Bending of a Centrally Loaded Plate supported at Two Opposite Edges, Prof. A. E. H. Love, 483

Bengal, Magic and Taboo in, Dr. B. Bonnerjea, 1033

Bengali Marriage and Cognate Customs, M. M. Chatterji, 998

Benzaldehyde, The Photolysis of, M. de Hemptinne, 926

Benzene: Hexabromide and Hexachloride, Crystal Structures of, R. G. Dickinson and C. Bilicke, 1000; Hydrocarbons, The Synthesis of, by means of Mixed Organomagnesium Compounds, L. Bert, 442; Ring, The Structure and Dimensions of the, J. K. Morse, 346

Benzil, The Dielectric Constant of, L. Saint-Antoine, 1006

Benzoic Acid and Cinnamic Acid, Determination of Small Quantities of, with some Notes on the Colorimetric Determination of Salicylic Acid, J. R. Nicholls, 264

Benzole Research Committee, Annual Report of the, 877

Berlin Technische Hochschule, Prof. G. Hertz appointed professor of physics at the, 226

Bessel Functions, A Series of, connected with the Lattice-points of an *n*-dimensional Ellipsoid, J. R. Wilton, 969

Beta Lyræ, Oscillations in the Period of, Miss M. A. Blagg, 512

Bicycle Pedalling, Dynamics of, S. Dickinson, 1005

Bifilar Oscillographs, The Adaptation of, to the Study of Triode Valves, A. Blondel, 850

Bimolecular Reactions in Solution, The Velocity Coefficient in, L. S. Kassel, 746

Binary Stars, Parallaxes of, deduced from Assumptions of their Mass, R. O. Redman, 183

Binocular Fusion of Colours, The, and its Relation to Theories of Colour Vision, S. Hecht, 890

Biochemical Sexual Dimorphism, W. H. Schopfer, 486

Biological: Flora of Britain, A Proposed, Dr. E. J. Salisbury, 170; Literature, Suggested Bibliographical Work on, 30; Statistical Data, Report of a Committee on, 294

Biology: before Darwin, 85; Experimental, Society for, Meeting of the, 31; of the Gulf of Mannar, Dr. F. H. Gravely, Dr. B. Sundara Raj, and others, 518; Readable School, O. H. Latter, 387
Biotite, The Phenomenon of Inversion in, Submitted to the Action of the α-rays, H. Jedrzejowski, 305
Birbirite, a New Rock, L. Duparc, E. Molly, and A. Borloz, 78
Bird: Feathers and the Antirachitic Vitamin D, Prof. W. Rowan, 323; Life: Realities of, being Extracts from the Diaries of a Life-loving Naturalist, E. Selous, with an Introduction by Prof. J. S. Huxley, 383; Sanctuaries in Royal Parks in Scotland, Second Annual Report on, 293; The Baby, and its Problems, W. Bickerton, 383; The Heart of a, A. Collett, 383
Birds: and Mammals, Nictitating Membrane of, E. P. Stibbe, 435; British, Manual of, H. Saunders. Third edition, revised and enlarged by Dr. W. Eagle Clarke, 613; of Eastern China (Chihli, Shantung, Kiangsu, Anhwei, Kiangsi, Chekiang, Fohkien and Kwangtung Provinces), A Handbook of the, J. D. D. La Touche. Part 2, 568; of the Island of Bute, The, J. M. McWilliam, 613; The Charm of, Viscount Grey of Fallodon, 383; The Practical Value of, Prof. J. Henderson, 447
Birmingham University: Annual Report of the Joint Standing Committee for Research, 226; Gift to, by Mr. and the Hon. Mrs. Anstruther-Gough-Calthorpe, 402; Contributions to, 1038
Birth Control Clinics, Society for the Provision of, Report of the, 334
Bismuth Crystals, The Study of the Specific Resistance of, Dr. P. Kapitza. Parts 1, 2, 3, 970
Bituminous: Coal, International Conference on, impending, at Pittsburgh, 334; Sands of Alberta, K. A. Clark and S. M. Blair, 72
"Blege," The, or Dwarf-salmon, K. Dahl, 427
Blind, Welfare of the, Advisory Committee on the, Seventh Report of the, 511
Blood: Arterial, The Comparative Toxicity of the Serum of, and that of Venous Blood, A. Lumière and Mme. R. H. Grange, 851; -Sucking: Insects in Relation to Blood Coagulation, Salivary Secretions of, Dr. Ll. Lloyd, 13; Midge, Mouth-parts of a, B. Jobling, 650
Blue Nile, The Upper Waters of the, Major R. E. Cheesman, 687
Bodleian Library, The, 471
Body Defence against Pathogenic Organisms, Caronia, 650
Bolivia, An Expedition to, 331
Book of Words: A, Selections from Speeches and Addresses delivered between 1906 and 1927, Rudyard Kipling, 614
Boronia, Four New Species of, with Notes on certain other Species, E. Cheel, 122
Borrowdale Volcanic Series in Troutbeck, etc., The Succession and Structure of the, G. H. Mitchell, 777
Botanical: Collection made by Capt. F. Kingdon Ward in the Eastern Himalaya and Tibet in 1924–25, The, C. V. B. Marquand, 265; Records in the Rocks, 564; Society of America, election of corresponding members; election of Prof. A. H. R. Buller as president, 255
Bottom-Sampler for Oceanographical Research, A New, Prof. M. Knudsen; Dr. A. C. Johansen, 225
Bouvet Island, a Radio and Meteorological Station to be established by Consul L. Christensen on, 510
Bowiea volubilis, Influence of Light on the form of, and the Increase and Structure of its Bulbs, W. Figdor, 607
Boyle medals of the Royal Dublin Society, award of, to Dr. W. R. G. Atkins and Prof. W. E. Adeney, 334
Brain, Higher Functions of the, The Physiology of the, Dr. D. Denny-Brown, 662
Brass: Bronze, and Aluminium-bronze, On the Quenching and Tempering of, Tsutomu Matsuda, 485; Ingots: Gases in, G. L. Bailey, 809; Influence of Dissolved Gases on the Soundness of 70 : 30, G. L. Bailey, 484
Brazil and Paraguay, A Zoological Expedition to, in 1926–1927, G. S. Carter, 889
Bread of our Forefathers: The, an Inquiry in Economic History, Sir William Ashley, 658
Bristol Museum and Art Gallery, Report of the, 961
British: Association: Sir Thomas Holland to be nominated as president for 1929, 394; The Charter of the, 661; The Glasgow Meeting of the, 833; Expedition to the Great Barrier Reef, Dr. C. M. Yonge, 213; Columbia, The Highest Peak in, to be named after Dr. G. M. Dawson, 432; Deer, Sir Herbert Maxwell, Bart., 6; East Africa, Economics and Administration in, Sir E. H. Leggatt, 68; Ecological Society, Annual Meeting of the, Dr. E. J. Salisbury elected president, 70; Electrical and Allied Industries Research Association, Report of the; Sir John F. C. Snell elected president of the, 254; Empire Cancer Campaign, forthcoming International Convention on Cancer Research, 111; Freshwater Algæ, A Treatise on the, in which are included all the Pigmented Protophyta hitherto found in British Freshwaters, the late Prof. G. S. West. New and revised edition, in great part rewritten by Prof. F. E. Fritsch, 614; Guiana, Geology of, S. Bracewell, 514; Industries Fair, 341; Industry and Trade, Movement of, 729; Journal Photographic Almanac and Photographers' Daily Companion, The, 1928, edited by G. E. Brown, 205; Medical Association, forthcoming meeting of the, 511; *Medical Journal*, retirement of Sir Dawson Williams; appointment of Dr. N. G. Horner as editor, 29; Museum (Natural History), additions to the, 181, 333, 509, 723, 1030; Antarctic (Terra Nova) Expedition, 1910. Natural History Report. Zoology, Vol. 7, No. 2: Polychæta, Prof. W. B. Benham, 856: Non-Ferrous Metals Research Association, Annual Report of the, 994; Rainfall, 1926, 88; Research Association for the Woollen and Worsted Industries, Appointments by the, 439; Col. the Hon. F. V. Willey elected chairman of the, 684; School of Archæology in Jerusalem, The, 993; Science Guild, Annual Report of the, 1029; Spas and Climatic Health Resorts, 649; Zoologists, Fifth Annual Meeting of, 69
Broadcasting: as an Aid to Scientific Study, 817; Stations, Identifying, Capt. Eckersley, 180
Bromine, Liquid, The Dielectric Constant of, Anne I. Anderson, 194
Bronze Age Urns from South Devon, H. G. Dowie, 221
Brooklyn Institute, the Children's Museum of the, Instruction for Scouts at, 112
Budde Effect, The, with Bromine Vapour and Air, E. Brown and D. L. Chapman, 809
Bud-scales, Morphology of, A. S. Foster, 1034
Building: Exhibition, The, 646; Research: P. L. Marks, 479; Board, Report of the, 479
Bulletin Géodésique, 1925–1927, 510
Burettes: A New Device for Reading, A. H. Baird, 884; 'Greasy,' W. Lowson, 14
Burma, Tertiary Igneous Rocks of, H. L. Chhibber; E. S. Pinfold, A. E. Day, L. D. Stamp, and H. L. Chhibber, 115
Burmese Myxophyceæ, Dr. S. L. Ghose, 686
Buru, Non-marine Mollusca of, Dr. T. Van Benthem Jutting, 964
Busch Microscopes, Catalogue of, 478
Butter: Fat, Composition of, A Seasonal Variation of the, P. Balavdine, 122; in Margarine, The Determination of, L. V. Cocks and E. Nightingale, 344

Cacao: Bean, Colour-producing Constituents of the Determination of the, W. B. Adam, 656; Tannin, H. R. Jensen, 521
Cadmium: Nitrate, Thermal Dissociation of, G. Malquori, 779; -silver Alloys, X-ray Analysis and Crystalline Structure of: G. Natta and M. Freri, 406, 559
Cæsium Cadmium Chloride $CsCdCl_3$, The Crystalline Structure of the Double, A. Ferrari and A. Baroni, 406
Caird, Sir James, Travelling Scholarships, foundation of, by Mrs. Emma Grace Marryat, 439
Cairo: Faculty of Medicine, Centenary of the, 67; School of Medicine, Clot Bey and the, Prof. M. Khalil; The Writer of the Notes, 747
Calcium in the Sun's Atmosphere, Pressure of, Prof. E. A. Milne, 1017
Calculus, Introduction to the, Prof. W. F. Osgood, 859

Calcutta, School of Tropical Medicine, etc., Annual Report of, 1031
Calendar of Customs and Festivals, 40, 77, 121, 156, 191, 227, 263, 303, 343, 403, 440, 482, 520, 557, 605, 655, 692, 732, 776, 813, 849, 888, 925, 968, 1004, 1039
Californian Miocene Mollusca, New, L. W. Wiedey, 920
Calories, The Two, P. L. Marks, 58; Dr. A. Russell; Prof. J. R. Partington, 170, 209
Cambridge University: H. L. H. H. Green appointed demonstrator in anatomy, 39; Prof. A. Hutchinson elected Master of Pembroke College; bequests by Sir Arthur Shipley, 155; W. B. R. King awarded the Sedgwick prize, 190; Dr. D. R. Hartree and T. M. Harris elected to fellowships at Christ's College; L. R. Jones elected to the Nita King scholarship; a proposal with reference to Girton and Newnham students, 226; the library building fund; award of the Gordon Wigan prize in chemistry to A. Caress and F. F. P. Smith; J. E. Littlewood appointed Rouse Ball professor of mathematics, 302; Dr. N. J. T. M. Needham appointed university demonstrator in biochemistry, 402; gifts to the Polar Research Institute; endowment of a studentship by Lady Walston; Miss S. M. Manton appointed university demonstrator in comparative anatomy; E. P. Waller appointed university lecturer in estate management. 439; L. F. Newman appointed university demonstrator in methods of agricultural analysis; G. F. Hickson appointed secretary of the Board of Extra-Mural Studies; grants from the Worts Fund to J. Steers and H. G. Carter; The Harkness scholarship in geology, 439; Dr. L. Brecher elected to the Yarrow research science fellowship at Girton College; award of Smith's prizes to W. L. Edge and A. H. Wilson; of Rayleigh prizes to J. A. Gaunt and W. H. M'Crea: grant for magnetic research work; the bequests of Dr. J. E. Blee, 481; E. J. H. Corner appointed Frank Smart student in botany; W. L. Edge awarded the Allen scholarship, 604; gifts for the Fitzwilliam Museum, 731; re-appointment of F. E. Baxandall and C. P. Butler as senior observers, W. Moss as junior observer, and H. E. Green as assistant observer at the Solar Physics Observatory, 775; W. H. McCrea elected to the Sheepshanks exhibition in astronomy; Report of the General Board of Studies; the position of mineralogy in the University; offer by J. S. Fry and Sons, Ltd., of a post-graduate studentship, 812; Research degrees of, 878; offer of a prize by Sir Archibald Denny, 887; gift towards the chair of astrophysics, 924; Dr. A. E. Barclay appointed lecturer in medical radiology and electrology; W. N. C. van Grutten appointed an assistant secretary to the Appointments Board, 924; Dr. T. C. Fitzpatrick elected Vice-chancellor; award of the John Winbolt prize to A. Callender, 967; C. Tate Regan and Dr. R. J. Tillyard elected honorary fellows of Queen's College; Prof. J. B. Buxton re-elected professor of animal pathology; T. G. Room and S. W. P. Steer appointed university lecturers in mathematics; C. Forster Cooper elected a fellow of Trinity Hall, 1003; Dr. D. R. Hartree appointed university demonstrator in physics; Dr. F. C. Phillips appointed university demonstrator in mineralogy; award of the Tyson medal to J. C. P. Miller, the Mayhew prize to M. J. Dean, the Rex Moir prize, the John Bernard Seely prize, and the Ricardo prize to H. L. Haslegrave, 1003
Canada: Prairie Provinces of, The Economic Development of the, Prof. Rodwell Jones, 68; Royal Society of, May meeting of the, 879; Water Powers of, 37
Cancer: 148; Mule-spinners', Dr. C. C. Twort and H. R. Ing, 722; Statistics, Dr. Janet Lane-Claypon and W. M'K. H. M'Cullagh, 396; Studies in Massachusetts (1), H. L. Lombard and C. R. Doering, 43
Candles and Lamps, W. Hough, 726
Cane Sugar: Modifications of, Prof. von Lippmann; Dr. Helderman, 35; The Synthesis of, Prof. A. Pictet and H. Vogel, 657, 689
Capacitance, The Measurement of, H. L. Curtis and C. Moon, 808
Caprokol: Antiseptic Solution, S. T. 37, British Drug Houses, Ltd., 652, 963
Carajura, Colouring Matters of, E. Chapman, A. G. Perkins, and R. Robinson, 338
Carbohydrate Metabolism, Insulin and, 260
Carbon: Atom in Crystal Structure, The Form of the, Miss I. E. Knaggs, 616; Dioxide: and Oxygen, Combustion of, Effect of Catalysts on the, Prof. W. E. Garner and C. H. Johnson, 772; Infra-red Emission of, C. R. Bailey and K. H. Lih, 941; in Soils, Determination of, A. Riad, 657; Liquid, The Surface Tension of, E. L. Quinn, 150; Tension in Tissues in Relation to Cancerous Cells, Dr. J. C. Mottram, 420; The Decomposition of, at Low Pressure under the Action of the Electric Current, P. Jolibois, H. Lefebvre, and P. Montagne, 861; Monosulphide, The Ultra-violet Band System of, etc., Dr. W. Jevons, 192; The Arc Spectrum of, Prof. A. Fowler and E. W. H. Selwyn, 304; The Disintegration of (3), H. Pettersson, 523
Carnegie: A New Cruise of the, 837; Cruise VII. of the, 1928–1931, Dr. J. A. Fleming and Capt. J. P. Ault, 871
Carnegie: Institution of Washington, Department of Terrestrial Magnetism, Annual Report, 723; Trust for the Universities of Scotland, Report of the, 691
Carnotite, Crystalline, F. L. Hess and W. F. Foshag, 397
Carotine and Sexuality, R. Chodat and W. H. Schopfer, 122
Carto-Bibliography and Kindred Subjects for Great Britain and Ireland, 1720 to 1927, Hand-List of Catalogues and Works of Reference relating to, Sir Herbert George Fordham, 937
Carvone in Dill Oil, The Determination of, Prof. J. Reilly and P. J. Drumm, 344
Caspian Sea, Level of the, Fluctuations of the, Prof. A. V. Voznesensky, 436
Castings, Flaws in, The Detection of, 845
Catalase and Plant Growth, J. E. Knott, 72
Catalysis, Heterogeneous, On the Present Position of the Theory of Centres of Activity in, Dr. F. H. Constable, 521
Catalytic Hydrogenation of the Phenols, The Mechanism of the, V. Grignard and G. Mingasson, 194
Cat-fishes, Three Rare, of the Magdalena River, Columbia, P. Schmidt, 815
Cathode Rays: Diffraction of, by Mica, S. Nishikawa and S. Kikuchi, 1019; Experiments on the Diffraction of, Prof. G. P. Thomson, 193
Caustic Curve formed by Refraction at a Plane Surface, On a Method of Constructing the, J. Smith, 405
Celebes, Ethnographical Studies in, Dr. W. Kaudern. Vol. 3: Musical Instruments in Celebes, 277
Cell, Microchemistry of the, Studies in the (1), Dr. R. J. Ludford, 228
Cellulose: and the Acetates of Cellulose, The Study of, by means of X-rays, J. J. Trillat, 733; Lacquers, R. A. Coolahan, 684
Central Mendips, The Geological Structure of the, F. B. A. Welch, 606
Cephalopoda: of the Irish Coast, The, Miss A. L. Massy, 485; The Branchial Gland of the, a Possible Endocrine Organ, G. E. Hutchinson, 674
Cephalopods, Differential Inhibition in the Development of, and Considerations on the so-called Axial Gradient, S. Ranzi, 306
Cepheid Variables, Analysis of, W. Zessewitsch, 296
Ceramiaceæ, The *bromuques* of certain, G. Ollivier, 890
Cereals, The Genetics of, Prof. R. R. Gates, 187
Cerebral Hemispheres, Physiology of the, Problems in the, Prof. I. P. Pavlov, 810
Cetacean, A Very Rare, on the Coast at Nettuno, G. Brunelli and G. Fasella, 658
Ceylon, The Rodents of, W. W. A. Phillips, 843
Ceylonese Waters, Marine Biology in, 261
Chætopterus, Artificial Production of Janus Embryo of, A. Titlebaum, 891
Chambers's Encyclopædia: a Dictionary of Universal Knowledge. New edition. Edited by Dr. D. Patrick and W. Geddie. Vol. 10, 205
Champion Potato, The Rejuvenation of the, W. D. Davidson, 693
Charles' University medal, award of the, to Prof. M. T. Bogert, 647

Chelsea Polytechnic, F. J. Harlow appointed Principal of, 1038
Chemical: Industry in Modern Life, 835; Society, nomination of officers, 432
Chemie, organischen, Lehrbuch der, Prof. P. Karrer, 857
Chemist, The, in the Photographic Industry, O. F. Bloch, 474
Chemistry: W. H. Barrett, 495; Applied: A Dictionary of, Sir Edward Thorpe, assisted by eminent contributors. Revised edition. Vol. 7. With an Index to the whole Work by Frances M. G. Micklethwait, 317; Reports of the Progress of. Vol. 12, 1927, 936; As a Career, 1; Culture and, 161; Elements of, Prof. H. N. Holmes and L. W. Mattern, 388; General, Theoretical and Descriptive, Prof. T. P. M'Cutcheon and Prof. H. Seltz, 133; Institute of, Annual General Meeting of the, 363; Organic: for Advanced Students, Prof. J. B. Cohen. Fifth edition. 3 Parts, 902; Modern, 857; Physical, A Revised, 612; Smith's Inorganic, Revised and Rewritten by Prof. J. Kendall, 388; The Romance of, Prof. W. Foster, 451; Theoretical, Outlines of, Dr. F. H. German. Fourth edition, 612
Chemotherapy: Principles and Practice of, with Special Reference to the Specific and General Treatment of Syphilis, Prof. J. A. Kolmer, 235; The Clinician and, 335
Cherries, Genetics of, C. D. Darlington, 397
Child Hygiene, Ante-Natal and Post-Natal, The Principles of, Dr. W. M. Feldman, 381
Chimique de l'or, La fabrication, J. Castelot, 981
China, The Birds of, Wilder, Gee, and Moffett, 919
Chinese: Art: and Handicraft, W. Burton, 378; One Hundred Plates in Colour . . . Introduced by an Outline Sketch of Chinese Art by R. L. Hobson, 378; Turkestan, Past and Present Peoples of, Sir Arthur Keith, 555
Chirocephalus diaphanus, The Feeding Apparatus of the Fairy Shrimp, Dr. H. G. Cannon, 558
Chloralose, The Pharmacological Action of, Prof. Swale Vincent and J. H. Thompson, 209
Chlorine, The Arc Spectrum of, O. Laporte, 1021
Chlorophyll in Solution, The Molecular Weight and Association of, N. Marinesco, 406
Cholesterol: and Vitamin D, Prof. S. M. Heilbron, Dr. R. A. Morton, and W. A. Sexton, 452; at Liquid Oxygen Temperature, The Activation of, Dr. C. E. Bills and F. G. Brickwedde, 452
Chondriome of a Fungus of the Genus Saprolegnia, The, P. Joyet-Lavergne, 559
Christ the Word, Dr. P. E. More, 704
Christ's Hospital, Horsham, proposed development of science teaching at, 1003
Chromium, Deposition of, the Applications, Properties, and the Methods of, S. Wernick, 219
Chromosomes, Homologous, A Working Hypothesis for Segmental Interchange between, Dr. J. Belling, 43
Circle and the Cross: The, a Study in Continuity, A. H. Allcroft. In 2 vols. Vol. 1: The Circle, 743
Circuit Breaking at High Pressures, Dr. Rengier, 223
Civil Engineers, Institution of: election as honorary members of, the Duke of York, Sir A. B. W. Kennedy, H. P. Macmillan, S. Rea, Sir Ernest Rutherford, and Lord Wemyss, 767; awards of the, 768; The Centenary of the, Eng.-Capt. E. C. Smith, 867; The Secretaries of the, 915; Centenary Conference of the, 945
Civil Service: Estimates, Class IV., Education, Science, and Art, 610; The Technical Expert in the, 737
Civilisation into Britain, The Introduction of, H. J. E. Peake, 188
Classical Association, Prof. D'Arcy W. Thompson elected president of the, 108
Classics of Modern Science (Copernicus to Pasteur), edited by Prof. W. S. Knickerbocker, 365
Clay, The Nature of, and its Significance in the Weathering Cycle, Prof. G. W. Robinson, 903
Clematis, A Comparative Study of the Stem Structure of the Genus, Edith Philip Smith, 305
Clepsydropsis australis, On, from the Carboniferous Rocks of Australia, B. Sahni, 1006
Clot Bey and the Cairo School of Medicine, Prof. M. Khalil; The Writer of the Notes, 747
Cloud, The Observation of, with Special Reference to the Safeguarding of Aviation, Dr. H. Hergesell, 143
Coal: Carbonisation: Tests, 921, 1000; High and Low Temperature: A Treatise on the Principles and Processes of Manufacturing Coke and Semi-Coke, J. Roberts, 201; in Great Britain: the Composition, Structure, and Resources of the Coalfields, Visible and Concealed, of Great Britain, Dr. Walcot Gibson. Revised Edition, 388; Mining Explosives, The safe use of, Dr. W. Payman, 722, 909; Seams of Northumberland and Durham, Dr. W. Hopkins, 920; the Formation of, Base Exchange and, Dr. E. McKenzie Taylor, 789; -Tar: Hydrocarbons, The Higher, Dr. A. E. Everest, 1013; The Minor Constituents of, 1013
Coals as Colloid Systems, Dr. L. L. Fermor, 705
Cobalt Chloride in Concentrated Hydrochloric Acid, The Analysis of the Absorption Spectrum of, W. R. Brode, 264
Cod-liver Oil, The Examination of Some Varieties of, in Wood's Light, H. Marcelet, 345
Cœlenterata, On Species among the, T. Stephenson, 41
Cœlostat, A New 18-inch, 247
Coffee: Mealy-bug in Kenya, The, T. W. Kirkpatrick, 686; Parchment as an Adulterant of Bran and Sharps, J. Evans and T. E. Wallis, 656
Coils for the Production of Strong Magnetic Fields, The Design of, J. D. Cockcroft, 483
Collenchyma cell-wall, The Structure of, deduced from Micro-chemical Investigations, D. B. Anderson, 230
Colloidal Solutions, Immunity of the Granule in, A. Boutaric and F. Banès, 814
Colombia, Mummies from, W. R. Dawson, 882
Colonial Agricultural Scientific and Research Service for the British Empire, Recommendations of a committee on the proposed, 429
Colonies, Secretary of State for the, appointments by the, 474, 647;
Colpoids, Thermotropism and Constants of the, A. L. Herrera, 78
Columbia University, New York, Professional Courses in Optometry at, 724
Combustion: Flame and, A. Egerton, 10; in mixtures of Hydro-carbons, The Propagation of, R. Duchêne, 345
Comet: A New, discovered at the Paris Observatory, Dr. H. Deslandres, 850; New, 335; The Recent Great, Dr. Slipher, and others, 113
Cometary Spectra, N. T. Bobrovnikoff, 769
Comets: 32, 395, 433, 512, 806, 881; The Spectra of, N. T. Bobrovnikoff; F. Baldet, 550
"Commutative Ordinary Differential Operators," Note on the paper by J. L. Burchnell and T. W. Chaundy, Prof. H. F. Baker, 304
Comparator, A, suitable for the Measurement of Filiform Spectra, M. Hamy, 1006
Complex Spectra, The Application of the Irregular Doublet Law to, K. Majumdar and G. R. Toshniwal, 828
Compositors and Readers at the University Press, Oxford, Rules for, H. Hart. The English Spellings revised by Sir James A. H. Murray and Dr. H. Bradley, Twenty-eighth edition, 533
Compound Functions, The Quasi-continuity of, G. Scorza-Dragoni, 1043
Compton Effect, The Optical Analogue of the, Prof. C. V. Raman and K. S. Krishnan, 711
Condensation Phenomena at Different Temperatures, 1042
Condensed and Dried Milks, The Labelling of, 181
Conditioned Reflexes: an Investigation of the Physiological Activity of the Cerebral Cortex, Prof. I. P. Pavlov. Translated and edited by Dr. G. V. Anrep, 662
Conifer Leaves, Seasonal Changes in, Prof. J. Doyle and Miss Phyllis Clinch, 258
Constantinople, Excavations at the Hippodrome, S. Casson, 513
Conversion in Science (Huxley Memorial Lecture), Prof. G. Elliot Smith, 750
Copepods: and Hydrogen Ion Concentration, A. G. Lowndes, 919; Observations of, Prof. A. Labbé, 393

Copper: –Nickel Alloy, Profound Alteration of a, by the Action of Steam Superheated to 350°-400° C., J. F. Saffy, 851; -Oxide Rectifier, The, 299; Sulphate in the Deacon Process, Rôle of, R. A. Beebe and D. B. Summers, 601; The Spark Spectrum of, A. C. Menzies, 1040
Coral Reefs: and a Migrating Anticline in Fiji, Prof. W. M. Davis, 185; of Tahiti, Moorea, and Rarotonga, C. Crossland, 484
Corals, The Lower Carboniferous, R. G. S. Hudson, 523
Corn from Egypt: The Beginning of Agriculture, Dr. M. Gompertz, 131
Cornell University, Dr. L. G. Romell appointed Charles Lathrop Pack research professor of forest soils in, 302
Corona: at High Humidity, On, A. W. Simon, 891; Photography of the, without an Eclipse, G. Blunck, 183; The Spectrum of the, I. M. Freeman, 169
Corpus Luteum, The, and the Cause of Birth, Prof. T. T. Flynn, 1020
Correlation, A. F. Dufton, 866

CORRESPONDENCE

Abetti, Prof. A., and the 1874 Transit of Venus, W. A. Parr, 675
Aeroplanes, Research on the Control of, Lt.-Col. W. L. Marsh, 939; Prof. B. Melvill Jones, 940
Alkali and Halogen Atoms, The Non-Appearance of the Recombination Luminescence in the Reaction between, V. Kondratjew, 571
Alloys, Hardness of, A. Mallock, 827
Ammonia, The Pure Rotation Spectrum of, R. M. Badger, 942
Argon, Ionised A II, The Spectrum of, Dr. T. L. de Bruin, 576
Astigmatism, The Correction of, Dr. T. J. I'a. Bromwich, 747
Aston Dark Space, The, Dr. K. G. Emeléus and Miss N. M. Carmichael, 14
Atomic Spectral Lines associated with the Band Fluorescence of Alkali Metals, The, Prof. J. C. McLennan and R. Ruedy, 500
Auroral Green Line in Active Nitrogen, Excitation of the, J. Kaplan, 711
Barley Varieties, Differential Response of, to Manuring, F. G. Gregory and F. Crowther, 136
Base Exchange and the Formation of Coal, Dr. E. McKenzie Taylor, 789
Beats by High-Frequency Interruption of Light, Prof. S. K. Mitra and D. Banerji, 573
Biological Flora of Britain, A Proposed, Dr. E. J. Salisbury, 170
Bird Feathers and the Antirachitic Vitamin D, Prof. W. Rowan, 323
Blood Coagulation, Salivary Secretions of Blood-sucking Insects in Relation to, Dr. Ll. Lloyd, 13
Cairo School of Medicine, Clot Bey and the, Prof. M. Khalil; The Writer of the Notes, 747
Calcium in the Sun's Atmosphere, Pressure of, Prof. E. A. Milne, 1018
Calories, The Two, P. L. Marks, 58; Dr. A. Russell; Prof. J. R. Partington, 170, 209
Carbon: Atom in Crystal Structure, The Form of the, Miss I. E. Knaggs, 616; Dioxide: Infra-red Emission of, C. R. Bailey and K. H. Lih, 941; Tension in Tissues in Relation to Cancerous Cells, Dr. J. C. Mottram, 420
Cathode Rays, Diffraction of, by Mica, S. Nishikawa and S. Kikuchi, 1009
Cephalopoda: The Branchial Gland of the, A Possible Endocrine Organ, G. E. Hutchinson, 674
Chloralose, The Pharmacological Action of, Prof. Swale Vincent and J. H. Thompson, 209
Chlorine, The Arc Spectrum of, O. Laporte, 1021
Cholesterol: and Vitamin D, Prof. I. M. Heilbron, Dr. R. A. Morton, and W. A. Sexton, 452; The Activation of, at Liquid Oxygen Temperature, Dr. C. E. Bills and F. G. Brickwedde, 452
Citric Acid, The Formation of, by *Aspergillus niger*, Dr. F. Challenger, L. Klein, V. Subramaniam, and Dr. T. K. Walker, 244
Clay, The Nature of, and its Significance in the Weathering Cycle, Prof. G. W. Robinson, 903
Clot Bey and the Cairo School of Medicine, Prof. M. Khalil; The Writer of the Notes, 747
Coal, Formation of, Base Exchange and the, Dr. E. McKenzie Taylor, 789
Coals as Colloid Systems, Dr. L. L. Fermor, 705
Compton Effect, The Optical Analogue of the, Prof. C. V. Raman and K. S. Krishnan, 711
Corona, The Spectrum of the, I. M. Freeman, 169
Corpus Luteum, The, and the Cause of Birth, Prof. T. T. Flynn, 1020
Correlation: A. F. Dufton, 866; Coefficients in Meteorology, E. V. Newnham, 421; Dr. R. A. Fisher, 712
Cosmic Rays, The Highly Penetrating, A. Corlin, 322
Crystal Reflection of X-rays entirely a Classical Phenomenon? Is, Prof. G. E. M. Jauncey and W. D. Claus, 983
'Dative' Chemical Bond, The, Prof. A. W. C. Menzies, 457
Density of a Luminous Gas, and the Emission of Light by Atoms in Metastable States, Prof. B. Venkatesachar, 356
Directional Wireless and Marine Navigation: the Rotating-Loop Beacon, Dr. R. L. Smith-Rose, 745
Dogfish without Pelvic Girdle or Fins, A, E. M. Sheppard and J. H. Lloyd, 540
Dug-out Canoe in Algoa Bay, Prof. E. H. L. Schwarz, 209; F. W. Fitzsimons, 540
Earth Currents and Terrestrial Magnetism, Dr. C. Chree, 242
Earth's: Atmosphere, Origin of the Semi-diurnal Pressure Wave in the, E. V. Newnham 353; Crust, The Thermal State of the, Dr. H. Jeffreys, 13
Echinoderms, Artificially-induced Metamorphosis in, Prof. J. S. Huxley, 10
Electrolysis, Strong, Dr. J. A. V. Butler, 500
Energy, Units of, F. J. W. Whipple, 355
Enzyme, The Affinity of Different Types of, for their Substrates, J. B. S. Haldane, 207
Ergosterol: Activation of, at – 180° C., T. A. Webster and R. B. Bourdillon, 502; as Parent Substance of Vitamin D, The Specificity of, Dr. O. Rosenheim and T. A. Webster, 570
Eruptive Rocks, Nomenclature of, Prof. S. J. Shand; The Reviewer, 324
Experimental growth *in situ*, On, X, 576
Explosions of Carbon Monoxide and Oxygen to which Hydrogen has been added, The Radiation from, Prof. W. E. Garner and F. Roffey, 56
Eyeglasses and the Microscope, T. H. T., 137; T. J. Briant, 209
Ferromagnetism, The Relation of Specific Heat to, Dr. J. R. Ashworth, 323
Fishiness in Dairy Products, The Cause of, W. L. Davies and A. T. R. Mattick, 324
Flame and Combustion, A. Egerton, 10
Flowering Plants, Genes and Chromomeres in, Dr. J. Belling, 831
Forestry and Agriculture in Great Britain, W. E. Hiley, 865; The Writer of the Article, 866
Gaseous Explosions, The Pressures Developed in, W. T. David and B. H. Thorp, 420
Gases: High Frequency Discharges in, Dr. S. P. McCallum, 353; The Disappearance of, into Glass under the Action of the Electric Discharge, J. Taylor, 708
Germ-plasm, The Trail of the, Dr. J. H. Orton, 352
Gibbs's, Willard, Works and Proposed Commentary, New Edition of, Prof. J. Johnston, Prof. W. F. G. Swann, and Prof. R. G. Van Name, 245
Golgi Bodies: in Plant Cells, Prof. J. B. Gatenby, 11; of Plants, The, Prof. J. B. Gatenby, 712; The Nature and Function of, Prof. C. Walker, 90, 279, 574; Dr. R. J. Ludford, 169, 456; Prof. J. B. Gatenby, 455
Grasses, Diseases of, caused by *Epichloë typhina*, Kathleen Sampson, 92
'Greasy' Burettes, W. Lawson, 14
'Green: Flash,' The, Sir Oliver Lodge, 58; Ray, Factors which Determine the Occurrence of the, Prof. R. W. Wood, 501; Sodium Band, The Excitation of the *D* Lines by the, E. L. Kinsey, 904
Gregory, James, John Collins, and Some Early Scientific Instruments, Prof. H. S. Allen; Dr. R. T. Gunther, 456

Gulf of Aden, Temperature and Salinity Observations in the, D. J. Matthews, 92
Helium : and the Genesis of Petroleum, Prof. C. C. Farr and M. N. Rogers, 938 ; Band Spectrum of : New Regularities in the, G. H. Dieke, Prof. T. Takamine, and T. Suga, 793 ; Prof. W. E. Curtis, 907 ;
Hevea brasiliensis, Yield Variability in, H. Ashplant, 1018
High : -frequency : Discharges, A Dark Space in, Dr. S. Smith, 91 ; Electric Discharge, A New Form of the, J. and W. Taylor, 171 ; Voltages in the Laboratory, The Production and Application of, G. Breit and M. A. Tuve, 535
Hund Theory, An Apparent Failure of the, Prof. A. G. Shenstone, 619
Hungarian Biological Research Institute, The, Dr. F. A. Bather, 93
Hybrid Vigour in Insects, The Evidence for, F. Muir, 56
Hydrodynamics, Postulates of, Major A. R. Low, 576
Hydrogen : Activation of, by Electric Discharge, G. Glockler, 93 ; Dr. G. A. Elliott, 985 ; R. W. Lunt, 357 ; Ion Concentration Changes in the Rusting of Iron, Lecture Experiments on the, Dr. W. R. G. Atkins, 615 ; Molecule : The, Prof. R. T. Birge, 134 , Prof. O. W. Richardson, 320 ; The Spectrum of the, Prof. O. W. Richardson and P. M. Davidson, 1018
Imperial Agricultural Research, Dr. A. C. D. Rivett, 14
India, Negrito Racial Strain in, B. S. Guha, 793
Inflammable Gas from Plants, F. C. Short, 172 ; W. A. Hamor, 283
Infra-red Solar Spectrum, Photography of the, H. D. Babcock, 830
Insects and Potato Virus Diseases, K. M. Smith, 904
Iodine Bands, Optically Excited, with Alternate Missing Lines, Prof. R. W. Wood and Prof. F. W. Loomis, 283
Ionised : Oxygen in the Gaseous Nebulæ, The Distribution of, J. H. Reynolds, 206 ; Ionised Sodium, Spectrum of, K. Majumdar, 432
Iron : 'Nitrides' of, X-ray Studies on the, Dr. G. Hagg, 826 ; Yttrium, and Lanthanum, Astrophysical Estimates of Ionisation Potentials of, A. V. Douglas, 906
Irregular Doublet Law : Extension of the, Prof. M. N. Saha and P. K. Kichlu, 244 ; The Application of the, to Complex Spectra, K. Majumdar and G. R. Toshniwal, 828
Kerr Effect, Disappearance and Reversal of the, Prof. C. V. Raman and S. C. Sirkar, 794
Latent Photographic Image, The Mechanism of Formation of the, Dr. F. C. Toy, 865
Lead Tetraethyl in Internal Combustion Engines, H. S. Rowell, 570 ; Dr. E. Mardles, 571
Leishmania tropica, The Exit of, through the Proboscis of *Phlebotomus papatasii*, Dr. S. Adler and O. Theodor, 282
Light : and Sight, T. Smith, 242, 706 ; Sir J. Herbert Parsons, 243 ; Dr. W. T. M. Forbes, 457 ; Prof. H. Hartridge, 617 ; Dr. F. W. Edridge-Green, 706 ; Scattering : A Change of Wave-length in, Prof. C. V. Raman, 619 ; at Critical Opalescence, Y. Rocard and M. Ponte, 746 ; Short Flashes of, Mechanical Production of, Dr. J. W. Beams, 863 ; -Year *versus* 'Parsec,' Dr. H. D. Curtis, 789
Liquid Stars, Prof. A. S. Eddington, 278 ; 496 ; Dr. J. H. Jeans, 279, 496
Lower Jaw of Cattle During Mastication, Movements of the, H. Riehm and E. A. Guggenheim, 357
Lucretius's Anticipation of Mendelism, Prof. R. C. McLean, 749
Luru Vopo Vir Can Utriet, R. Steele, 208
Magic Squares, Formation of, Subsidiary Rectangles as applied to the, Major J. C. Burnett, 57, 172, 985
Mammoths and Man in the Transvaal, Dr. R. Brown, 324 ; Prof. H. F. Osborn, 672
Marsh Gas from Plants, Prof. A. Findlay, 58
Martensite, Two Kinds of, Prof. K. Honda and S. Sekito, 744
Mercurous Chloride of Standard Purity, Luminescence of, Prof. J. Křepelka, 457
Mercury : -Thallium Molecule, Investigation of a, R. K. Waring, 675 ; The Band Spectrum of, excited by a High Frequency Discharge, J. G. Winans, 863 ; Vapour, Fluorescence of. Prof. R. W. Wood and V. Voss, 418
Methylene Blue Penetrate Living Cells ? Does, Dr. M. Irwin, 939
Milk Pasteurisation and the Tubercle Bacillus, L. J. Meanwell, 712
Milton and Modern Science, C. L. Barnes, 831
Mnemotropism : Persistence Tendency in Remembering, Dr. J. H. Kenneth, 423
Monomolecular Films, Dr. S. E. Sheppard and R. L. Keenan, 982
Natural Reactivity and the Origin of Species, Prof. A. R. Olson and Prof. G. N. Lewis, 673
Nebulium : and Hydrogen in New Stars, B. P. Gerasimovič, 422 ; Spectrum : in New Stars, The, S. R. Pike, 136 ; C. T. Elvey, 453 : The Density necessary to produce the, C. T. Elvey, 12 ; The, Prof. J. C. McLennan and R. Ruedy, 319 ; Prof. D. H. Menzel, 618 ; The Origin of the, Prof. Meghnad Saha, 418
Negrito Racial Strain in India, B. S. Guha, 793
Neon : The Spark Spectrum of, Prof. H. N. Russell, Prof. K. T. Compton, and J. C. Boyce, 357 ; Tubes : New Type of Discharge in, J W. Ryde, L. Jacob, and B. S. Gossling, 794 : F. A. Long, 1020
Nierenstein Reaction. The, Dr. M. Nierenstein, 940
Nile and Faiyum in Pliocene and Pleistocene Times, The Relations of. Dr. K. S. Sandford and W. J. Arkell, 670
Nitrogen : Active : Dr. E. J. B. Willey, 355 : Dr. B. Lewis, 864 ; J. Kaplan and G. Cario, 906 ; Dr. B. Lewis, 938 ; P. K. Kichlu and D. P. Acharya, 983 ; Afterglow : The, Prof. J. C. McLennan, R. Ruedy, and J. M. Anderson, 537 ; Dr. S. P. McCallum and W. E. Perry, 942
North Sea, Rare Fishes in the, Prof. E. Ehrenbaum, 709
Nova Pictoris, Dr Spencer Jones, 862
Oldoway Skull, The, L S. B. Leakey, 499
Optical Paradox, An, T. Smith, 281, 536 ;, Dr. N. R. Campbell ; Dr. L. F. Richardson. 536 ; J. W. Perry, 749
Origin of Species, Natural Reactivity and the, Prof. A. R. Olson and Prof. G. N. Lewis, 673
Ostrea, The Dominant Species of, Dr. J. H. Orton, 320
Ovarian Hormone, The, Dr. B. P. Wiesner, 498
Oxfordshire Flowers and the Plot Memorial Windows, Dr. G. C. Druce, 93
Oxide Films, Passivity and Protective, U. R. Evans, 351
Peacock's 'Eye,' The Colour of the, Lord Rayleigh, 827
Periodic System of Elements, Anomalous Groups in the, Prof. E. Fermi, 502
Personal and Impersonal Styles in Scientific Communications, Dr. N. R. Campbell, 1021
Petroleum : Base Exchange and the Formation of, Dr. M. Stuart, 940 ; Genesis of, Helium and the, Prof. C. C. Farr and M. N. Rogers, 938
Photochemical Clustering, Dr. B. Lewis, 792
Photoelectric : Cells, Red Sensitive, C. C. Paterson, 58 ; Photometer, A Simple Form of, Dr. J. H. J. Poole, 281
Photoelectrons Produced by X-Rays, Spatial Distribution of, E. J. Williams, 134
Physics and Metaphysics, W. W. L., 984
Pike, A Voracious, Sir Herbert Maxwell, 908
Pleochroic Haloes and the Age of the Earth, Dr. F. Lotze, 90 ; Prof. J. Joly, 207
Potato Virus Diseases, Insects and, K. M. Smith, 904
Prices of Periodical Scientific Publications, Dr. Baini Prashad, 499 ; F. C. Nicholson, 749 ; W. Bonser, 538
Quantum Postulate, The, and Atomic Theory, F. J. Selby, 828
Radio Waves, Polarisation of, J. Hollingworth and R. Naismith, 171
Radium E, The Disintegration of, from the Point of View of Wave Mechanics, Prof. G. P. Thomson, 615
Rainbow Visible after Sunset, B. M. Peek, 985
Rainfall : Interception by Plants, Dr. J. Phillips, 354 ; Law, A Simple, H. Jameson, 170
Rana temporaria, The Urinogenital Organs of the Male Frog, J. H Lloyd, 423
Rubber Latex, A New Injection Mass—, D. R. R. Burt, 497
Salmon, Land-locked, C. Tate Regan, 502
Salt : Crystals as Nuclei of Sea Fog Particles, Sir Napier Shaw, 866 ; Uncommon Common, A. F. Dufton and C. G. Webb, 942
Science : and Nature, Dr. J. E. Turner, 617 ; St. G. Lane Fox Pitt, 748 , Teaching in Schools, E. Nightingale ; A. K. Goard, 453, 572 : F. S. Young ; H. E. A., 454 ; R. Weatherall, 572

Scientific Terminology and its Annexation, J. L. Dunk, 137
Sea Fog Particles, Salt Crystals as Nuclei of, Sir Napier Shaw, 866
Secondary Radiation, A New Type of, Prof. C. V. Raman and K. S. Krishnan, 501
Segmental Interchange and Crossing-over, Dr. J. Belling, 282
Selenium, Bubbles of, Production of, Major C. E. S. Phillips, 172
'Self-Adaptation,' Use of the Term, in Biology, Dr. E. E. Fournier d'Albe, 14; W. W. L., 172
Silver Halides, The Inner Photoelectric Effect with, Dr. S. E. Sheppard, 574
Sligo: Artefacts, The: A. L. Armstrong, M. C. Burkitt, H. Dewey, Miss D. A. E. Garrod, and R. A. Smith, 137; Dr. L. S. Palmer, J. W. Jackson, and W. O'B. Pierce, 501; J. Reid Moir, 908; Implements, Geological Features of the Sites of the, Prof. O. T. Jones and Prof. P. G. H. Boswell, 861; The Palæolithic Implements of, J. Reid Moir, 57, J. P. T. Burchell, 983
Sodium, Ionised, The Spectrum of, O. Laporte, 941
Soft X-Ray Emission and Absorption Spectra with Tangential Grating, Dr. J. Thibaud, 321
Soil 'Stratometer': The, A Method for the Examination of Deep-lying Soil, Moh^{ed} Zaghloul, 537
Solar Corona, Spectra of the, The Origin of the, Prof. Meghnad Saha, 671
Sonic and Ultrasonic Waves, Transmission of, through Partitions, Prof. R. W. Boyle, 55
Spanish Fowl, White-faced, Altered Character in the, F. Finn, 246
Spectra, The Excitation of, by High Frequency Oscillations, M. Ponte, 243; J. R. Clarke, 282
Spinax niger Cloquet, The Luminescence of the Dogfish, C. F. Hickling, 280
Splanchnic Nerves, Functional Differences between Left and Right, J. H. Thompson, 540
'Sports': and 'Reversion', Prof. M. Drummond; The Writer of the Notes, 575; Photographs, Apparent Distortion in, Dr. T. J. I'a. Bromwich, 829
Square Roots and the Decimal System, C. E. W. Dodwell; A. R., 907
Stark: Components of Hα, Observed Relative Intensities of, Dr. J. S. Foster and M. Laura Chalk, 830; Effect and Series Limits, Dr. Jane M. Dewey and Dr. H. P. Robertson, 709
Stars in Planetary Nebulæ, Temperatures of, H. Zanstra, 790
Stellar: Photographs, Use of Diffraction Effects in Measurements of, Prof. A. Pollard, 246; Radiation: What becomes of? Prof. B. Brauner, Dr J. H. Jeans, 674; and the Nature of the Universe: Sir Oliver Lodge, 711: W. W. L., 749
Sun Images through Window Glass, Prof. S. Russ, 58
Surface Tension of Solids, Experimental Measurement of the, Dr. G. N. Antonoff, 93
Tar, Low Temperature, The Constituents of, Prof. E. Bornstein, 356; Prof. G. T. Morgan and D. D. Pratt, 357
Thames Floods: H. Harries, 708; P. J. H. Unna, 942
Transvaal, Mammoths and Man in the: Dr R. Brown, 324, Prof. H. F. Osborn, 672
Ultra-Violet: Microscopy, Dr. L. C. Martin, 419; Transmission of New Glasses, Prof. W. E. S. Turner, 831
Velocity Coefficients for Bimolecular Reactions in Solution, L. S. Kassel, 746
Venus, The 1874 Transit of, Prof. A. Abetti and, W. A. Parr, 675
Vision and Reality, O. Reiser, 575
Vitamin D, Bird Feathers and the Antirachitic, Prof. W. Rowan, 323
Weighing, Devices for increasing Accuracy in, F. C. Guthrie, 745
Whale, The Pulmonary Circulation of the, R. W. Gray, 905
Whales: The Blubber of, R. W. Gray, 791; The Buoyancy of, R W. Gray, 421, 710, 984; T. H. Taylor, 576; Sir Sidney F. Harmer, 748; Capt. G. C. C. Damant, 829
Wireless: Waves: Short, The Polarisation and Fading of, T. L. Eckersley, 707; The Scattering of, T. L. Eckersley, 245; Woods and Dr. B. Rolf, 539; R. H. Barfield, 908
Woods and Wireless: Dr. B. Rolf, 539; R. H. Barfield, 908
X-ray Reflection, The Polarisation Factor in, R. W. James, 422
X-rays in Various Elements, Absorption of, Dr. E. Jönsson, 283
Zinc and Cadmium, Single Crystals of, Magnetic Properties of, Prof. J. C. McLennan, R. Ruedy, and Elizabeth Cohen, 351
Zoological Nomenclature, Amendments to the International Rules of, Dr. C. W. Stiles, 12

Corrosibilities of Ferrous and Non-Ferrous Metals and Alloys, The Relative, Part I., Dr. J. Newton Friend, 484
Corsica: Eastern, New Geological Observations in, P. Termier and E. Maury, 851; The Altimetry of, P. Helbronner, 970
Cosmic Rays, Prof. R. A. Millikan and Dr. G. H. Cameron, 477, Prof. R. A. Millikan and Dr. G. H. Cameron and Dr. J. H. Jeans on, 723; New Results on, Prof. R. A. Millikan and Dr. G. H. Cameron, 19, 29; The Highly Penetrating, A. Corlin, 322
Cosmogony, The Wider Aspects of, Dr. J. H. Jeans, 433, 462, 463
Cost of Living of a Sample of Middle-class Budgets, The, D. Caradog Jones, 926
Cotton: A Bacterial Disease of, R. E. Massey, 909, Industry, Research in the, edited by Dr. R. H. Pickard; Prof. W. E. Morton, 493; Research and Industry, 561
Crangon vulgaris, The Abdominal Muscular Systems of the Common Shrimp, R. J. Daniel, 434
Crassulaceæ, Materials for a Revision of, S. Schonland, 927
Creator Spirit: The, A Survey of Christian Doctrine in the Light of Biology, Psychology, and Mysticism, Rev. Canon C. E. Raven. With an Appendix on Biochemistry and Mental Phenomena, by Dr. J. Needham, 200
Cremanthodium (Compositae), The Geography of the Sino-Himalayan Genus, R. D'O. Good, 777
Croce: Benedetto, An Autobiography, translated by R. G. Collingwood, 1016
Crocker Land, The Problem of, 883
Croonian Lecture, The, Prof. I. P. Pavlov, 810
Croydon Aerodrome, Developments at the, 683
Crystal: of α-iron, The Behaviour of a Single, subjected to Alternating Torsional Stresses, Dr. H. Gough, 192; Organic, The Structure of an, Sir William Bragg, 471; Reflection of X-rays entirely a Classical Phenomenon? Is, Prof. G. E. M. Jauncey and W. D. Claus, 983; -Structure Models, Stereoscopic Photographs of, Dr. A. E. H. Tutton, 75; Surfaces, 666
Crystalline: Diffraction, Spectrography of the X-rays by, Frilley, 305, Lens, Ultramicroscopic Investigations on the (3), D. Cattaneo, 306; Network of Micro-Crystalline Substances, Determination of the, by means of Radiograms taken with Powders, Gallard, 606;
Crystals: of β-brass, The Deformation of, G. I. Taylor, 192; The Chemical Properties of (May Lecture of the Institute of Metals), Prof. C. H. Desch, 766; the Etch Figures on, The Nature, Origin, and Interpretation of, Prof. A. P. Honess, 666
Cuba, The Soils of, H. A. Bennett and R. V. Allison, 859
Cucumis melo, The Growth of Seedlings of the Cantaloup, in the Absence of Exogenous Food and Light, Prof. R. Pearl, Agnes Allen Winsor, and J. R. Miner, 658
Cucurbitaceæ, Fruit-rot of Cultivated, Mitra and Subramaniam, 883
Culture and Chemistry, 161
Currency and Credit, R. McKenna, 804
Curtisia Faginea Ait. ('Assegaai'), J. F. V. Phillips, 927
Cuvier et Lamarck: Les classes zoologiques et l'idée de série animale (1790–1830), Dr. H. Daudin. 2 Vols.: Vol. 1, 85
Cyanite, Al_2SiO_5, The Structure of, W. H. Taylor and W. W. Jackson, 1041
Cyclohexene, Condensation of, with Some Aromatic Hydrocarbons in the Presence of Aluminium Chloride, D. Bodroux, 814
Cyclonic Depressions, The Development of, W. J. Humphreys, 690

Cyclo-Hexane, The Photo Bromination of, B. J. Wood and Dr. E. K. Rideal, 116
Cyclops, Variability in, Z. Koźmiński, 807
Cyrtandropsis, A New, in the Hawaiian Islands, B. P. G. Hochreutiner, 927
Cytology, Czechoslovakian, Prof. J. B. Gatenby, 610
Cytoplasmic Inclusions, Nature of, Prof. J. B. Gatenby, 164

Dallebura Tribe, The, North Queensland, M. Bennett, 686
Daly, Charles P., gold medal of the American Geographical Society of New York, presented to Prof. A. Musil, 597
Dams, Construction of, Mesnager and Veyrier, 73
Danish: -Icelandic Expedition to Iceland, 1927, The Second, Dr. N. Nielsen, 95; Plaice Investigations in the Baltic Sea, 775
Darwin, George, lecturer of the Royal Astronomical Society, W. H. Wright appointed, 295
Darwinism, Implications of, Sir Arthur Keith, 993
Dasychira pudibunda, A Bacillus Parasite of the Caterpillars of, E. Hubault, 851
'Dative' Chemical Bond, The, Prof. A. W. C. Menzies, 457
Davy Faraday Research Laboratory, Dr. A. Muller appointed assistant director of the, 432
Daylight: Artificial Light, and Artificial Daylight, J. S. Dow, 724; in Buildings, 116

DEATHS.

Deep Sea Fishes, New, A. E. Parr; C. M. Breder, Jr., 297
Deer: Hunting and Stalking the, the Pursuit of Red, Fallow, and Roe Deer in England and Scotland, L. Edwards and H. F. Wallace, 6
Dentistry, the Use of X-rays in, 841
Deportation, Eugenical Aspects of, Dr. H. H. Laughlin, 876
Derivatives, Generalised, and Integrals, W. L. Ferrar, 522
Descartes, René, La géométrie de, 702
Desert Dunes, Limits of Form and Magnitude in, Dr. Vaughan Cornish, 620
Determinant, The Structure of a, Major P. A. MacMahon, 965
Déterminants supérieurs, Coup d'œil sur la théorie des, dans son état actuel, M. Lecat, 417
Developer Stains, Lumière and Seyewetz, 688
Development Commission, The, Seventeenth Report of, 18
Diamonds, Artificial Production of, The Problem of, 799
Diazo-compounds, Action of Light on, A. Seyewetz and D. Mounier, 778
Dictyoxylon cortex of Lycopodiales as a constituent of Coal, The, C. A. Seyler, 1006
Didinium nasutum, Some Effects of Dietary Insufficiency in the Ciliate, C. D. Beers, 785
Dielectric Phenomena: Electrical Discharges in Gases, S. Whitehead. Edited with a Preface by E. B. Wedmore, 162
Dielectrics, the Dielectric Constant of, The Action of Radio-active Radiation on, G. Guében, 733
Diesel-Electric Locomotives, 1035
Diet, The Influence of, upon the Teeth, 325
Differential: Equations of Mathematical Physics, The General Integrals of Some, G. Wataghin, 695; und Integralrechnung, Vorlesungen über, Prof. R. Courant. Band I: Funktionen einer Veranderlichen, 451
Digitin of Nativelle, The, P. Bourcet and G. Dugue, 443
Dilute: Sulphite Solutions, the Titration of, with Standard Iodine Solutions, H. M. Mason, 265; Solutions, Measurement of the Concentration of, R. Macy, 398
Dinas Mawddwy (Merioneth), The Geology of the District around, W. J. Pugh, 345
Diphenylamine and Diphenylnitrosamine, Estimation of, in the Presence of their Derivatives, Prof. H. Ryan, J. Keane, and J. Dunne, 1042
Diphenylparaffins, Preparation of Certain α- ω-, V. Ipatiev, N. Orlov, and B. Dolgov, 814
Direct Current Machines, The Performance and Design of, Dr. A. E. Clayton, 54
Direction Finding in Navigation, T. H. Gill and N. F. S. Hecht, 189
Directional Wireless and Marine Navigation: the Rotating-Loop Beacon, Dr. R. L. Smith-Rose, 745
Discharge-tube Physics, 450
Discovery Expedition, Whaling Research and the Work of the, Dr. S. W. Kemp, 558, 795; N. A. Mackintosh, 798
Dissolved Gases from Water, An Improved Apparatus for the Removal of, Lorch, Williams, and Thompson, 337
Distillation Flask, A Novel, 299
Dogfish: A Cirripede Parasite from the, Prof. J. Johnstone and Miss W. E. Frost, 434; without Pelvic Girdle or Fins, A, E. M. Sheppard and J. H. Lloyd, 540
Dolomites of South Tyrol, The, Prof. W. Solomon-Calvi, 83
Domestic Fowl, The Relation of Gonadic Structure to Plumage Characterisation in the (4), A. W. Greenwood, 1006
Domme and its Surrounding Country, Miss Moya Jowett, 473
Doubly Charged Positive Ions in Gases, On the Duration of the Existence of, and their Detection, L. B. Loeb, 43
Douglas Fir in Britain, Diseases of the, 479
Drama in Hull and District, Evolution of the, T. Sheppard, 317
Drayson Paradox, The, 395
Drops, The Terminal Velocity of, W. D. Flower, 733
Drugs and Alkaloids, The Action of, on Pulse Beats of Plant and Animal, Sir J. C. Bose, 995
Druids: The, A Study in Keltic Prehistory, T. D. Kendrick, 204
Dublin University, Conferment of honorary doctorates on Dr. G. L. Streeter and Prof. A. S. Eddington, 481
Dug-out Canoe in Algoa Bay, Prof. E. H. L. Schwarz, 209; F. W. FitzSimons, 540
Dumortierite in Grains: The Identification of, Dumortierite in Cornish Granite, A. W. Groves, 656
Durham: Castle, Prof. A. Holmes, 966; University, Dr. W. A. Waters appointed a lecturer in chemistry, 120
Dust in the Air of Paris, The Visibility and Amount of, L. Besson, 734
Dutch Elm Disease and Its Occurrence in England, The, M. Wilson and Miss M. J. F. Wilson, 656
Dying People, A Record of a, Dr. A. C. Haddon, 411

ε Aurigæ: 685; Minimum of, Miss Cecilia H. Payne, 598
Early Man in East Anglia, 275
Earth: Age of the, Pleochroic Haloes and the, Prof. J. Joly, 207; Currents and Terrestrial Magnetism, Dr. C. Chree, 242; On the Rotation of the, and Astronomical Time, Prof. W. de Sitter, 99, 108; Rotate? Does the, W. Edgell, 981; Shock in North Staffordshire, F. J. Rathbone, 217; The Outer Shells of the, Prof. R. A. Daly, 552; The, the Sun, and the Moon, Dr. G. Forbes, 1015; The Velocity of the, E. Brylinski, 158
Earthquake: in Italy, 432; Reported large, 432; on March 16, 474; on March 22, 510; on April 16, 648; on May 21, 768; on May 14, 840; on June 1, 917; on June 15, 994; on June 21, 1031
Earthquakes: on March 26, 27, and 31, 548; Recent, 682; in the Crimea in 1927, Prof. A. V. Voznesensky, 690; in Bulgaria and Greece, Dr. C. Davison, 716; The Focal Depth and Origin of, K. Suyehiro, 808; The Lunar Periodicity of, 920
Earth's: Crust: Pulsations of the, T. Matuzawa, 72; The Thermal State of the, Dr. H. Jeffreys, 13; Rotation, Variation in the, 1032
Earthworms, The Storing of, by Moles, M. Degerbøl, 297
East: Africa, Ghosts in, G. W. B. Huntingford, 843; African: Agricultural Research Institute, Appointments at the, 429; Earthquake of Jan. 6, 1928, W. C. Simmons, 844; Anglia, The Antiquity of Man in, J. Reid Moir, 275; London College, Commemoration of the, 838
Easter: Day, fixing the date of, 256, 291, 994, 1032; The Date of, and other Christian Festivals, Rev. D. R. Fotheringham, 902
Eastern Adepts and Western Science, Dr. J. Stephenson, 4
Ebro Observatory, The, Father Puig, 685
Échinodermes des mers d'Europe, Les, Prof. R. Koehler. Tome 2, 52
Echinoderms: Artificially-induced Metamorphosis in, Prof. J. S. Huxley, 10; of the British Isles, Handbook of the, Dr. T. Mortensen, 52
Eclipse: The Total, of August 31, 1932, Dr. L. J. Comrie, 256; Total, Radio Observations during, H. S. Jelstrup, 73
Ectodermal Placodes in the Head Region of a Sparrow Embryo, F. Goldby, 476
Ectoparasitic Trematode, A New, Dr. G. A. MacCallum, 114
Ecuador, Eastern, A New Volcano in, J. H. Sinclair, 880
Edinburgh University: award of the Cameron prize to Prof. C. Levaditi, 120; the retirement of Sir James Walker; bequest by J. Sanderson; impending foundation of a Wallace prize, 190; Prof. J. Kendall appointed professor of chemistry, 342; Dr. A. E. Cameron appointed lecturer in medical entomology in, 519; Dr. F. A. E. Crew appointed professor of animal genetics, etc., 848; Forestry Society, The, 877
Edison medal, award of the, to Dr. W. D. Coolidge, 182
Education: and Industry, 45; for the Adolescent in Yorkshire, 155
Educational: Colonies Associations, The Plan of the, Capt. J. W. Petavel, 39; Process, The Quality of the, Dr. W. S. Learned, 262; Settlements Association, Report of, for 1926–27, 654

Eels ascending the Rivers in the Eastern part of the Mediterranean, The Limited Numbers of Young, G. Athanassopoulos, 734
Egg Grading and Marketing Scheme, A New, 334
Eggs, Frozen, The Microbial Flora of, J. Verge and E. Grasset, 657
Egypt, Archæological Investigations in, 1029
Egyptian Royal Mummies, Proposal as to, Sidky Pasha, 255
Einstein : Bending of Light, Another Test of the, 220, Deflexion of Light in the Eclipse of September 1922, The, Prof. W. W. Campbell and R. J. Trumpler, 769 ; Delusion, The, and other Essays, L. A. Redman, 979
Elasmobranch Oils, Glycerides in, Composition of the Fatty Acids Present as, Prof. T. P. Hilditch, 521
Elder Berry, The Nature of the Pigment of the, T. J. Nolan and M. T. Casey (1), 777
Electric : Arcs in Closed Vessels, The Pressures produced by, G. Allsop and Prof. R. V. Wheeler, 515 ; Currents in Telephone and Telegraph Conductors, The Propagation of, Prof. J. A. Fleming. Fourth edition, 167, Discharge, On a New Effect in the, Prof. T. R. Merton, 30[illegible] ; Furnaces in Metallurgy, Birmingham Electric Furnaces, Ltd., 728 ; Locomotives, New, 478 ; Phenomena, The Influence of Gravitation on, Prof. E. T. Whittaker, 41 ; Waves, Anomalous Dispersion and Absorption of, S. Mizushima, 116
Electrical : Conductivity, W. V. Houston, 884 ; Disturbances in Cables, Hughes, 150 ; Energy : and that of Coal By-Products, The Production of, W. T. Townend, 509 ; The Foreign Transmission of, M. Genissieu, 877 ; Engineers, Institution of : award of premiums, 841 ; *Journal* of the, January, 112 ; Lt.-Col. K. Edgcumbe elected president of the, 960 ; Equipment, Automatic Operation of, 596 ; Hardening and Annealing Processes, 688 ; Illumination, Modern, C. Sylvester and T. E. Ritchie, 377, Indicator for High-speed Engines, An, J. Obata and Y. Yosida, 553 ; Research and Development, 130 ; Resistance Measurements, H. Nakamoura, 259
Electricity : Act of 1926, Interlinking under the, 333 ; at the London Zoo. Mrs. Lawson, 684 ; Domestic Applications of, 338 ; Scheme for Central England, The, 509 ; The Interchange of, between Thunderclouds and the Earth, B. F. J. Schonland, 193 ; The Storage and Discharge of, F. W. Peek, 647
Electro : -Farming : or the Application of Electricity to Agriculture, R. B. Matthews, 742 ; -Steel Furnaces, Arc Type, 150
Electrocapillary Microphone, An, M. Latour, 345
Electrodeless Discharge, Recent Spectroscopic Applications of the, G. Dejardin, 657
l'Électrodynamique : Quelques idées sur théories nouvelles sur l'oscillateur de Planck et le mouvement autonome exposées devant la Société française de Physique, R. Ferrier, 450
Electrolysis of Water by an Alternating Current, The, Canaud, 657
Electrolytes : Space Charges in, Prof. A. Coehn and Dr. Schnurmann, 186 ; Strong, Dr. J. A. V. Butler, 500
Electromagnetic Phenomena, The Influence of Gravitation on, Prof. E. T. Whittaker, 1022
Electromotive Force in a Photoactive Cell, On the Variation of the, containing a Fluorescent Electrolyte, with the Intensity of Illumination, W. Rule, 891
Electron : Emission in Intense Electric Fields, R. H. Fowler and L. Nordheim, 969, The Quantum Theory of the part 2, P. A. M. Dirac, 304 ; The, the α-Particle, and the X-Ray, 414 ; The Wave Equation of the, Prof. C. G. Darwin, 969 ; The Waves of an, Prof. G. P. Thomson, 959 ; Theory of Metals and Thermionic Formulæ, The Restored, R. H. Fowler, 264
Electronic Theory of Valency, The, Dr. N. V. Sidgwick, Prof. T. M. Lowry, [illegible]27
Electrons : among Atomic Levels, On the Distribution of, E. C. Stoner, 522 ; and Molecules, Collisions between, Dr. I. Langmuir and H. A. Jones, 772 ; from Cold Conductors in Intense Electric Fields, On the Extraction of, Prof. O. W. Richardson, 264 ; in Gases, The Motion of, R. d'E. Atkinson, 483 ; in Ionised Media, Scattering of, Dr. I. Langmuir, 186 ; passing through Fine Slits, Some Experiments with, Prof. R. Whiddington, 522 ; passing through Hydrogen, The Energy Losses of, H. Jones and Prof. R. Whiddington, 522 ; Symmetry in the, P. Vinassa, 559 ; The Diffraction of, C. Davisson and L. H. Germer, 149 ; The Scattering of, in a Thin Aluminium Foil, P. Tartakovsky, 815 ; Total Reflection of, O. Klemperer, 553
Electrostatics in a Gravitational Field, On, E. T. Copson, 264
Elektrische Bodenforschung : ihre physikalischen Grundlagen und ihre praktische Anwendung, Dr. W. Heine, 936
Elektrizitatslehre, Einfuhrung in die, Prof. R. W. Pohl, 240
Elektromagnetische Feld : Das, ein Lehrbuch, Prof. E. Cohn. Zweite Auflage, 450
Elektrostatische Versuche mit Anwendung des Universalelektroskops, T. Wolff, 788
Elements, Artificial Disintegration of, W. Bothe and H. Franz, 651
Embryonen, Blut und blutbildende Organe menschlicher, Dr. W. Knoll, 417
Emigration within the British Empire, 929
Emission Spectrum, The Continuous, produced by the Electrodeless Discharge, G. Balasse, 405
Empetrum, Sex Chromosomes in, O. Hagerup, 726
Empire : Cotton Growing Corporation, Quarterly Report of the, 362 ; Marketing Board, Publication of the, 295
Energy : from the Sea, Obtaining, G. Claude, 926 ; in Molecules, The Distribution of, L. S. Kassel, 658 ; of a Body Moving in an Infinite Fluid, with an Application to Airships, The, Prof. G. I. Taylor, 1040
Engine Knock and Related Problems, A. C. Egerton, 876
"Engineering Degree Series," The, 120
Engines, Prof. E. N. da C. Andrade, 284
Entomology, International Congress of, forthcoming, 431
Environment and Race : a Study of the Evolution, Migration, Settlement, and Status of the Races of Man, Prof. Griffith Taylor, 532
Enzyme, The Affinity of Different Types of, for their Substrates, J. B. S. Haldane, 207
Eocene Mollusca, English, A. G. Wrigley, 435
Ephemeroptera and Plecoptera, The Ova and Oviposition of some, E. Percival and H. Whitehead, 522
Equilibrium, Figures of, of a Heterogeneous Fluid Mass, R. Wavre, 657
Erbium, The Purification and Atomic Weight of, A. E. Boss and B. S. Hopkins, 728
Ergosterol : Activation of, at −180° C., T. A. Webster and R. B. Bourdillon, 502 ; The Specificity of, as Parent Substance of Vitamin D, Dr. O. Rosenheim and T. A. Webster, 570
Eros, Preparations for the near approach of, in 1931, 475
Erosion by Water-hammer, S. S. Cook, 1040
Errors, Law of, On some Misapplications of the, and on the Intrinsic Error in Focometry, T. Smith, 305
Eruptive Rocks, Nomenclature of, Prof. S. J. Shand ; The Reviewer, 324
Erythræa scilloides, 808
Ethane : Molecule, The Structure and Dimensions of the, J. K. Morse, 659 ; some Simple Derivatives of, An X-ray Study of, part 1, K. Yardley, 193 ; The Lattice Structure of, J. K. Morse, 659
Ether, the Potential of the, R. Pictet, 78
Ethnology, Hypothetical, Dr. A. C. Haddon, 665
Ethyl : Alcohol, The Action of, on the Renal Secretion, A. Galamini, 231 ; Amino-malonate, R. Locquin and V. Cerchez, 971 ; Phenylethylmalonate, The Saponification of, by Alkalis, E. Tassilly, A. Belot, and M. Descombes, 306
Ethylene, The Rectilinear Diameter of, E. Mathias, C. A. Crommelin, and H. G. Watts, 41
Ethylenethiocarbamido-salts, Complex, of Univalent and Bivalent Metals, Prof. G. T. Morgan and F. H. Burstall, 553
Etiolation of Shoots for Cuttings, Dr. Edith Smith, and others, 1002
Etruscan Language, The, Prof. Trombetti, 647
Eucalypts in Scotland, J. A. B. Macdonald, 298
Eugenics Review, New Series, 840
Eugénique, La question, dans les divers pays, Dr. M. T. Nisot. Vol. 1, 495
Euler, Léonard, et ses amis, Prof. L.-G. du Pasquier, 786

Euphyllopod Crustaceans, The Circulating Elements of the Hæmolymph of, C. Artom, 306
Europäischen Schlangen, Die: Kupferdrucktafeln nach Photographien der lebenden Tiere. Dr. F. Steinheil. Siebentes Heft. Herausgegeben von Prof. L. Müller. Tafeln 31, 32, 33, 34, 35, 859
European: Corn Borer, Parasites of the, D. W. Jones and D. J. Caffrey, 397; Echinoderms, Dr. F. A. Bather, 52
Evans, Lewis, Collection of Scientific Instruments at Oxford, Annual Report of the, 393
Evolution, 840, 995
Evolution: and its Modern Critics, Sir Arthur Keith, 253; Truth and Error in the Doctrine of, Dr. J. A. Fleming, 252
Experimental: Biology, Society for, Easter Conference of the, 597; Growth *in situ*, On, X., 576; Phonetics, International Society of, Foundation of, and election of officers, etc., 841
Experimentalphysik, Handbuch der, Herausgegeben von W. Wien und F. Harms. Band 14: Kathodenstrahlen, P. Lenard und A. Becker; Kanal-strahlen, W. Wien, 450; Band 21: Anregung der Spektren, spectroskopische Apparate, G. Joos und E. v. Angerer; Stark-effekt, J. Stark, 741
Exploration, Adventures of, Book 6: North America, Sir John Scott Keltie and S. C. Gilmour, 241
Explosions of Carbon Monoxide and Oxygen to which Hydrogen has been added, The Radiation from, Prof. W. E. Garner and F. Roffey, 56
Explosive Wave: Influence of the Temperature on the Formation of the, P. Laffitte, 778; The Velocity of the, P. Laffite and P. Dumanois, 306
Eyeglasses and the Microscope: T. J. Briant, 209; T. H. T., 137

Fall Army Worm, The, P. Luginbill, 770
'Fallen Stars' of the Benghazi Steppe, D. V. Zanon, 771
Falsified Documents, The Photographic Detection of, Prof. C. Bonacini, 223
Far Eastern Association of Tropical Medicine, The Seventh Congress of the, Dr. J. Stephenson, 339
Faraday: Lecture, The, of the Institution of Electrical Engineers, Dr. S. Z. de Ferranti, 430; Medal of the Institution of Electrical Engineers, award of the, to Prof. J. A. Fleming, 143; Annual Meeting, Prof. T. M. Lowry elected president, 880
Faraday's: Law, The Validity of, for Currents due to Ionisation by Collision, P. Kobeko and I. Kurchatov, 815; Note-books, From, Sir William Bragg, 218, 254, 293
Fats and Waxes, The Industrial Chemistry of the, Prof. T. P. Hilditch, 205
"Fauna; of British India" Series, Dr. J. Stephenson appointed editor of the, 111; of the Empire, Society for the Preservation of the, Aims of the, 765
Faune de France: 15; Diptères (Nématocères), Chironomidæ, Tanypodinæ, M. Goetghebuer; 17: Diptères (Brachycères), (Asilidæ), E. Séguy, 386; 16: Polychètes sédentaires; addenda aux errantes, Archiannélides, Myzostomaires, Prof. P. Fauvel, 856
Federated Malay States, The production of animals and birds in sanctuaries and reserves, the destruction of noxious animals, 548
Fellāhīn of Upper Egypt: The, Their Religious, Social, and Industrial Life of To-day, with Special Reference to Survivals from Ancient Times, Winifred S. Blackman, 380
Felsted School Scientific Society, Report of the, 959
Female Sexual Hormone in Aqueous Form, The Biological Actions of the, E. Steinach, M. Dohrn, W. Schöller, and W. Hohlweg, 266
Ferromagnetic Substances, The Specific Heats of, L. F. Bates, 192
Ferromagnetism, The Relation of Specific Heat to, Dr. J. R. Ashworth, 323
Ferro-nickels containing Chromium, The Electrical Properties of, P. Chevenard, 486
Field Currents: from Points. Prof. Millikan and others, 965; Relations of, to Thermionic Currents, Prof. R. A. Millikan and C. C. Lauritsen, 659
Fight against Disease, Spring No., 961
Film Catalysts, Surface Area of, A New Interference Method of Measuring the, Dr. F. H. Constable, 1041
Finsbury Technical College, On, Prof. H. E. Armstrong, 439
Finsler's Comet, 1924 II., The Orbit of, V. G. Siadbey, 694
Fire and Bark-beetle Attack, Injury by, J. M. Miller and J. E. Patterson, 602
Firedamp, The Estimation of, 514
Fish Mortality in Fresh Waters, Major R. B. S. Sewell; Dr. B. Chopra, 807
Fisheries: and their Products, 603; of Madras, 887
Fishiness in Dairy Products, The Cause of, W. L. Davies and A. T. R. Mattick, 324
Fison Memorial Lecture, The, Sir William Bragg, 471
Flame and Combustion, A. Egerton, 10
Flies, The Hereditary Transmission of the Size and Weight of, resulting from Inanition, P. P. Sacharov, 815
Flora of Oxfordshire, The, Dr. G. C. Druce. Second edition, 858
Florida, a Smithsonian expedition to, 331
Flow of Water in Pipes of Rectangular Section, The, S. J. Davies and C. M. White, 1041
Fluid Resistance to Moving Spheres, R. G. Lunnon, 404
Fluids, Some Cases of Instability of, Dr. H. Jeffreys, 264
Fluorescence: Apparatus for the Investigation of, Dr. F. W. Müller, 337; of Chlorochrome in Ultra-violet Rays, The, G. T. Dragone, 79
Flying: -Boat Flight to Karachi, The, 332; The Physiological Effects of, Group-Capt. M. Flack, 986
Fogs and Clouds, W. J. Humphreys, 205
Folkestone Natural History Society, Jubilee of the, 547
Food: -Fishes of St. Andrews Bay, Prof. W. C. McIntosh, 148; Species, Certain, Chemical Composition of, L. Settimj, 229
Foot-and-Mouth Disease, the prevention of the introduction of from South America, 547
Forces of a Body placed in a Curved or Converging Stream of Fluid, The, Prof. G. I. Taylor, 1040
Foremanship Training, Lt.-Col. H. Diemer, 614
Forestry and Agriculture in Great Britain: 697; W. E. Hiley, 865; The Writer of the Article, 866
Formaldehyde: and Carbon Monoxide, The Absorption Spectra of, V. Henri and S. A. Schou, 850; and Sugars, The Formation of, by the Action of Ultra-violet rays on Alkali and Alkaline Earth Bicarbonates, G. Mezzadroli and G. Gardano, 79; in Solution, The Absorption Spectrum of, S. A. Schou, 657
Formosa, Anthropometry in, A. Matsumura and E. Miyauchi, 114
Forthcoming Books of Science, 390
Fossil Medusa, A, V. Van Straelen, 687
Foster Parent - Foster Child Comparisons as Evidence upon the Nature-Nurture Problem, Barbara Stoddart Binks, 346
Fowl: -pox and Vaccinia: Cytological Studies on the Viruses of, Dr. R. J. Ludford, 228; Immunological and Serological Studies on the Viruses of, G. M. Findlay, 228; The Relation of Gonadic Structure to Comb Growth in the, J. S. S. Blyth, 485
Fox Indians, Ceremonial Runners of the, T. Michelson, 33
Frankland, Edward, Prof. H. E. Armstrong, 840
Fraser Anthology, A, 855
Freiberg, Dr. O. S. Kutzer appointed professor of the geology of fuel and director of the fuel institute at the School of Mines, 76
French Alps, The Common Sides of the Fundamental Italian Triangulation and the Detailed Geometrical Description of the, P. Helbronner, 733
Frequency Curves and Correlation, W. P. Elderton. Second edition, 1016
Fresh- and Salt-water Fishes, Parasites of, Physico-chemical Researches on Some, W. H. Schopfer, 78
Freshwater: Algæ of Africa, The, Prof. F. E. Fritsch and Florence Rich (7), 890; Fossil Mollusca from the Argentine, Doello-Jurado, 34
Friendship, the flight of the, 1028
Frog, The Biology of the, Prof. S. J. Holmes. Fourth edition, 384
Fuel Testing in Canada, 115
Fundamental Frequencies, Interatomic Forces and Molecular Properties, J. R. Bates and D. H. Andrews, 735

Fundulus Embryos, Application of Experimental Methods to the Study of Developing, J. S. Nicholas, 43
Fundulus, The Action of Na, K, and Ca Chlorides on the Egg of, J. H. Bodine, 43
Fungi, The Structure and Development of the, Dame H. C. I. Gwynne-Vaughan and B. Barnes, 742
Fungoid Mycosis, Parasite of, The Transmissibility to the Animal of the, F. Wyss-Chodat, 657
Fūrie Kyūsū oyobi Sekibun Ron, being a Japanese translation of H. S. Carslaw's "Introduction to the Theory of Fourier's Series and Integrals." Translated by G. Takemae, 88
Furunculosis in the Salmonidae, I. J. F. Williamson, 485
Fuses, The Action of, P. D. Morgan, 809

γ-rays, The Internal Conversion of, B. Swirles, 192
Galactic System, The Structure of the, Dr. Seares, 725
Galapagos Islands, Basalts of the, H. S. Washington and Mary G. Keyes, 298
Galleria Mellonella, L'Infection microbienne et l'immunité chez la mite des abeilles, S. Metalnikov, 822
Galton Lecture, The, Dr. C. J. Bond, 291
Galvanometer and Fluxmeter Constants, etc., A Simple Graphic Method for the Determination of, A. Ferguson and E. J. Irons, [illegible]04
Gambusia Holbrooki, The rôle of the Viviparous American Fish in the Struggle against Paludism in Corsica, E. Brumpt, 734
Gamma-Rays from Potassium Salts, Prof. W. Kolhorster, 149
Gas: Cycle Transforming into Energy the whole of the Heat Furnished to the Cycle, A, R. Pictet, 78; Light and Coke Company, the Activities of the, 111; Mixtures, The Molecular Displacements in Diffusing, Prof. S. Chapman, 969; Natural, Development of, Col. S. J. M. Auld, 601; Study of the, obtained by Cracking Oil, for Lighting for Coast Beacons, R. Delaplace, 158; Town, The Compression of, J. Chappuis and A. Pignot, 158
Gaseous: Bearings, E. Henriot and E. Huguenard, 299; Combustion: at High Pressures, Part 9, Prof. W. A. Bone, D. M. Newitt, and C. M. Smith, 193; D. M. Newitt (Pt. 10), 1041; Explosions, The Pressures Developed in, W. T. David and B. H. Thorp, 420; Ions in H_2S-H_2 mixtures, The Mobilities of, L. B. Loeb and L. Du Sault, 735
Gases into Glass, The Disappearance of, under the Action of the Electric Discharge, J. Taylor, 708
Geiger: α-particle Counter, On the Action of the, J. Taylor, 850; Electrical Counter, Use of the, Dr. N. Riehl, 223
Gelatine, The Magnetic Susceptibility and Second Supposed Isoelectric Point of, M. Fallot, 926
Genes and Chromomeres in Flowering Plants, Dr. J. Belling, 831
Geneva, Post-Glacial Mollusca of, Dr. J. Favre, 114
Geodesy: A Formula useful in, A Generalisation of, P. Dive, 694; A Useful Formula for, R. Wavre, 78
Geodetic Tables, A. R. Hinks, 844
Geographical Association, Presidential Address to the, Dr. Vaughan Cornish, 309
Geography: and Anthropology, Dr. A. C. Haddon. 532; Teaching, Need for a New Approach in, Dr. Marion I. Newbigin, 68
Geological: Map of Europe, A, 918; Society: awards of the, 112; election of officers, 394; Survey: of Great Britain and the Museum of Practical Geology, Summary of Progress of the, 224; Scotland, Memoirs of the; The Oil-Shales of the Lothians. Third Edition. Part 1: The Geology of the Oil Shales Fields, R. G. Carruthers, based on the work of H. M. Cadell and J. S. Grant Wilson. Part 2: Methods of Working the Oil-Shales, H. Caldwell. Part 3: Chemistry and Technology of the Oil-Shales, E. M. Bailey. Part 4: History of the Scottish Oil-Shale Industry, H. R. J. Conacher, 276
Geology in Great Britain, 224
Geometrical: Optics, T. Smith, 436; Representation of the Mass of a Material Point in a Universe of Five Dimensions, The, A. Schidlof, 78
Geometrie: analytischen, Lehrbuch der, Prof. L. Heffter und Prof. C. Koehler. Band I: Zweite Auflage, 937
Géométrie: infinitésimale, Éléments de, Prof. G. Julia, 451; Les bases de la, et de la physique: l'invariance de l'espace euclidien, O. Lawiès, 534; non-euclidienne, La, Prof. P. Barbarin. Trois. édition. Prof. A. Buhl, 534; problèmes de, Examen des différentes méthodes employées pour résoudre les, G. Lamé, 417
Geophysical: Prospecting: in Australia, 179; Prof. A. S. Eve, 359; Surveying, Discussion on, 548
Geophysics: Applied, Methods of, for the Exploration of Oil, Ores, and other Useful Deposits, Dr. E. Pautsch, 936
Geophysik: Die magnetischen Verfahren der angewandten, Dr. H. Haalck, 936; Lehrbuch der, Herausgegeben von Prof. B. Gutenberg. Lief. 4, 748
Germanous Salts, The Preparation and Properties of some, J. Bardet and A. Tchakirian, 606
Germ-plasm, The Trail of the, Dr. J. H. Orton, 352
Gibbs, Willard: Gold medal, award of the, to Prof. W. D. Harkins, 1031; New edition of Works and proposed Commentary, Prof. J. Johnston, Prof. W. F. G. Swann, and R. G. Van Name. 245
Gibraltar, Straits of, Water Movements in the, Prof. R. de Buen, 555
Glacial Retreat from Central and Southern Ireland, The, Prof. J. K. Charlesworth, 438
Glasgow: Royal Philosophical Society, election of officers, 511; Royal Technical College, Report of, for 1926-1927, 556; University, conferment of a doctorate on Dr. R. C. Smith, 691
Glass: Molten, Conductivity of, F. F. S. Bryson, 73; Research on, 1035; Stamps and Weights: Illustrated from the Egyptian Collection in University College, London, Sir Flinders Petrie, 311; The Constitution of, a Series of Papers reprinted from the Journal of the Society of Glass Technology, edited by Dr. W. E. S. Turner, 239; The Elastic Constants of, E. P. Perman and W. D. Urry, 814
Glasses, New, Ultra-violet Transmission of, Prof. W. E. S. Turner, 831
Glozel: Finds, The, Sir Arthur Evans, 68; Investigations, The, 17
α-Glucoheptulose, The Ketonic Function of, G. Bertrand and G. Nitzberg, 889
Glucose: The Oxidation of, in Alkaline Solution by Oxygen and by Atmospheric Air, M. Nicloux, 890; The Reducing Power of, S. A. Schou and R. Wurmser, 442
Glycuronic Acid in Wines made from Diseased or Mouldy Grapes, The Presence of, D. Chouchak, 523
Gmelins Handbuch der anorganischen Chemie, Achte Auflage. System-Nummer 2: Wasserstoff, 204
God is Love. Can this be True? An Old Man's Meditations, Dr. J. M. Wilson, 534
Goitre in School Children, Dr. P. Stocks, 71
Gold: and Silver in Sea Waters, The Estimation of, M. Yasuda, 338; Coast: Colony and Protectorate, Survey in the, 651; Forests, The, Dr. T. F. Chipp, 301; Purple (2), C. G. Fontana, 306
Golden: Age: The, the Story of Human Nature, H. J. Massingham, 131; Eagle: Days with the, Seton Gordon, in collaboration with his wife, 384; The Book of the, Capt. C. W. R. Knight, 384
Goldsmiths' Company, Sir William J. Pope elected Prime Warden of the, 917
Golgi: Apparatus of Protozoa, The, Dr. S. D. King, 148; Bodies: in Plant Cells, Prof. J. B. Gatenby, 11; of Plants, The, Prof. J. B. Gatenby, 712; The Nature and Function of, Prof. C. Walker, 90; Dr. R. J. Ludford, 169; Prof. C. Walker. 279; Prof. J. B. Gatenby, 455; Dr. R. J. Ludford, 456; Prof. C. Walker, 574
Grapes, Growth of, Studies in the, Part, 6, P. R. v. d. R. Copeman, 42
Grasses, Disease of, caused by *Epichloe typhina*, Kathleen Sampson, 92
Gravitation, The Influence of, on Electromagnetic Phenomena, Prof. E. T. Whittaker, 1022
Gravity: A New Method for the Absolute Determination of, by the Pendulum, C. Volet, 850; Survey by Submarine, Dr. V. Meinesz, 34
Gray, Thomas Lowe, lecture, Prof. C. J. Hawkes, 188
Great Barrier Reef, British Association Expedition to the, Dr. C. M. Yonge, 213: 69, 197, 837

Greece, Excavations at Dendra, A. J. B. Wace, 364
Greek, Ancient, Physical Types, Prof. J. L. Myres, 966
Green: Auroral Line, The, J. Kaplan, 772; Flash, The, Sir Oliver Lodge, 58; Ray: Explanation of the, F. Ruda, 79, 306; Occurrence of the, Factors which Determine the, Prof. R. W. Wood, 501; Sodium Band, The Excitation of the *D* Lines by the, E. L. Kinsey 904
Greenland, The Expeditions to, of the University of Michigan, Prof. W. H. Hobbs, 42
Greenwich, Royal Observatory, Annual Visitation of the, Dr. A. C. D. Crommelin, 923
Gregorian Calendar in Egypt, The, 335
Gregory, James, John Collins, and Some Early Scientific Instruments, Prof. H. S. Allen; Dr. R. T. Gunther, 456
Growth, Intra-seasonal Cycles of, H. S. Reed, 890
Guiana Jungles, A Naturalist in the, Prof. S. H. Williams, 122
Gypsy Marriage, T. W. Thompson, 963
Gyroscopic Apparatus, A New, for Preventing Rolling of Vessels, J. Fieux, 305

Hake, The Natural History of the, C. F. Hickling, 599
Hall Effect in Iron Crystals, The, Dr. W. L. Webster, 35
Halley Lecture delivered by Dr. H. Shapley, 1038
Hardness and Temperature, E. G. Herbert, 35
Harmonic: Analysis and the Interpretation of the Results of Periodogram Investigations, D. Brunt, 850; Curves, A. E. Donkin, 150
Harmony as a Principle of Mathematical Development, G. A. Miller, 890
Hartmann Test, The 'Absolute,' R. Kinglake, 483
Hartree's Atomic Fields, A Theory of, J. A. Gaunt, 521
Harvard College Observatory, The Boyden Station of the, re-established near Bloemfontein, 393
Harvey: Tercentenary, The, 834; William, M.D., A Bibliography of the Writings of, Dr. G. Keynes, 835
Harvey's "De Motu Cordis," tercentenary of the publication of, 802
Hawaiian: Barnacles, H. A. Pilsbury, 686; Jaws and Teeth, H. G. Chappel, 396; Somatology, Dr. C. Wissler, 476
Health: Good, and Happiness: a New Science of Health, J. Ellis Barker. With an Introduction by Sir W. Arbuthnot Lane, 369; Personal, Prof. E. R. Hayhurst, 369; Towards, Prof. J. A. Thomson, 369
Healthy Growth: a Study of the Relation between the Mental and Physical Development of Adolescent Boys in a Public Day School, Dr. A. A. Mumford, 369
Heat furnished to a Gas, Integral Transformation into Motive Power of the, R. Pictet, 406
Heaviside Layer, Movements of the, R. A. Heising, 772
Heirlooms of Industry in the Science Museum, Col. Sir Henry G. Lyons, 1024
Helico-conical Vortices, U. Cisotti, 559
Helium: and the Genesis of Petroleum, Prof. C. C. Farr and M. N. Rogers, 938; Band Spectrum of: New Regularities in the, G. H. Dieke, Prof. T. Takamine, and T. Suga, 793; Prof. W. E. Curtis, 907; The Structure of the, Prof. W. E. Curtis, 404; in Deep Diving and Caisson Working, Prof. J. H. Hildebrand, Dr. R. R. Sayers, and W. P. Yant, 577; Liquid States of, Two Different, Prof. W. H. Keesom and M. Wolfke, 158; The Distribution of Intensity in the Band Spectrum of, the Band $\lambda 4650$, W. H. J. Childs, 404
Hemimysis Lamornae, The Embryology of a Mysid Crustacean, S. M. Manton, 228
Herbarium and Timber Specimens, The Collection and Preparation of, J. B. Davy and L. Chalk, 788
Heredity and Human Affairs, Prof. E. M. East, 415
Herring Investigations at Plymouth, E. Ford, 1036
Hesperopithecus, Dr. W. K. Gregory, 148
Hevea Brasiliensis: Seasonal Variations in the Composition of the Latex of, N. Rae, 344; Yield Variability in, H. Ashplant, 1018
High-frequency: Discharges: A Dark Space in, Dr. S. Smith, 91; in Gases, Dr. S. P. McCallum, 353; Electric Discharge: A New Form of the, J. Taylor and W. Taylor, 171; at Low Pressures, The, J. Taylor and W. Taylor, 850; Sound Waves of Small Intensity and their Biological Effects, Prof. E. N. Harvey and A. L. Loomis, 622; Temperature Equilibria, H. Prescott, Jr., and W. B. Hincke, 223; Tension Cables, Stresses on, 335; Voltages in the Laboratory, The Production and Application of, G. Breit and M. A. Tuve, 535
Highland Schists of Middle Deeside and East Glen Muick, The, H. H. Read, 522
Histological Changes encountered in the Naphthalene Cataract when the Crystalline Fibres are examined in a Surviving Condition, A. Busacca, 79
Holothurian, Digestive Enzymes of a, E. Sawano, 808
Home Office Industrial Museum and Exhibits, Descriptive Account and Catalogue of the, 597
Hops: New Varieties of, Prof. E. S. Salmon, 258; The Brewing Values and Antiseptic Powers of, J. J. H. Hastings and T. K. Walker; A. H. Burgess and H. Martin, 298
Hornblende, Common, The Effect of Heat on, S. Kozu, A. B. Yoshiki, and K. Kani, 298
Host and Parasite, late Prof. L. Harrison, 1043
Houben's Reaction, L. Bert, 559
Huddersfield Technical College, Dr. W. B. Crow appointed head of the biology department at the, 691
Hull, University College: F. G. Tryhorn appointed professor of chemistry in, 262; further gift by T. R. Ferens; A. C. Hardy appointed professor of zoology, 76; laying the foundation-stone of the, 731
Human: Enamel, The Chemical Evidences of the Organic Content of, E. Sprawson and F. W. Bury, 228; Nutrition, Problems in, 609; Variability: Elementary Conditions of, a Study of the Variation of Successive Responses to Similar Stimula, at Different Levels of the Cerebro-spinal System of a Human Subject, Prof. R. Dodge, 380
Humid and Non-Humid Weaving Sheds, Sickness in, A. B. Hill, 434
Humidity Test Equipment, E. B. Wood, 186
Hund Theory, An Apparent Failure of the, Prof. A. G. Shenstone, 619
Hungarian Biological Research Institute, The, Dr. F. A. Bather, 93
Hunter: John, the bicentenary of: 110; Sir Arthur Keith, 210; Dr. William, the career of, 802
Huxley: Memorial: Lecture, Prof. G. Elliot Smith, 750; medal of the Royal Anthropological Institute, award of the, to Baron Erland Nordenskiöld, 549; -Wilberforce Debate, The, Prof. E. B. Poulton, 839
Hybrid Vigour in Insects, The Evidence for, F. Muir, 56
Hydrocarbons: starting with Propyl Alcohol, The Formation of, A. Mailhe and Renaudie, 345; The Slow Combustion of, S. Landa, 559
Hydrodynamics, Postulates of, Major A. [illegible] Low, 576
Hydrogen: activated by the Electric Discharge, A. de Hemptinne, 778; Activation of, by Electric Discharge, Dr. G. A. Elliott, 985; G. Glockler, 93; R. W. Lunt, 357; and Carbon Dioxide, Absorption of Ultra-sonic Waves by, T. P. Abello, 43; and Chlorine, The Photochemical Union of, L. Harris, 659; and Mercury, The Behaviour of, at the Electrode Surfaces of Spectrum Tubes, M. C. Johnson, 404; and Oxygen, The Kinetics of the Combination of, C. N. Hinshelwood and H. W. Thompson, 264; Inflammability of, Studies on, Yoshio Tanaka and Yuzaburo Nagai, 299; Ion Concentration Changes in the Rusting of Iron, Lecture Experiments on the, Dr. W. R. G. Atkins, 615; Molecule: and of Helium, The Diamagnetic Susceptibility of, in the New Quantum Mechanics, S. C. Wang, 346; The: Prof. O. W. Richardson, 320; Prof. R. T. Birge, 134; Ionised, Prof. A. H. Wilson, 304; Spectrum of the, Prof. O. W. Richardson and P. M. Davidson, 1018; Secondary Spectrum of, Intensity Measurements in the, L. S. Ornstein, W. Kapuscinski, and J. G. Eymers, 304; The Continuous Spectrum of, J. Kaplan, 230; The Inflammability of, Y. Tanaka and Y. Nagai, 688; Vapour, The Chemical Constant of, and the Failure of Nernst's Heat Theorem, R. H. Fowler, 304
Hydrolysis, Velocity of, and Hydrogen Ion Concentration, H. Colin and Mlle. A. Chaudun, 306
Hydrometry, Electrical Methods of, R. W. Burbridge and N. S. Alexander, 484

Hyperallantoinuria in Artificially Produced Polyuria and Diabetes in Man, A. E. y Costa, 606

I. stellenbossiensis, A. Duthie, from the Stellenbosch Flats, A. V. Duthie, 927
Ice: Age, The, A. H. Bailey, 395; Drifts and Seal-fishing, Dr. T. Iversen, 71, 297
Iceland: Birds of, A Handbook of the, Masa U. Hachisuka, 669; South-east, The Major Intrusions of, Hilda K. Cargill, L. Hawkes, and Julia A. Ledeboer, 521
Igneous Rocks, A Classification of, E. T. Hodge, 72
Immortality, Personal, Why I believe in, Sir Oliver Lodge, 978
Immunization: Local, Specific Dressings, Prof. A. Besredka. Edited and translated by Dr. H. Plotz, 382
Imperial: Agricultural Research, Dr. A. C. D. Rivett, 14; 781; Chemical Industries, Ltd.: Progress of, 915; The Significance of, Major A. G. Church, 973
Incinerating Furnace, A New, Dr. Fortnet, 845
India: and the Pacific, A. M. Hocart, 551; Linguistic Survey of, Sir George Abraham Grierson. Vol. 1, Part 1, 783; Railway Electrification in, 333; Science and Policy in, Major A. G. Church, 698; The Languages of, Prof. R. L. Turner, 783; Zoology in, Major R. B. S. Sewell, 476;
Indian: Agriculture, The development of, A. Howard and Gabrielle L. C. Howard, 698; Cottons, Textile Properties of, A. J. Turner, 337; Fish, Drawings of, Dr. S. Lal Hora, 770; Fossil Suidæ, Dr. Pilgrim, 435; Science Congress: Fifteenth Session of the, 401; Presidential Address to the, Dr. J. L. Simonsen, 216; Trematodes, New, Dr. E. C. Faust, 434
Indigotin from Indol, Formation of, by Soil Bacteria, P. H. H. Gray, 157
Induction Furnace, A Valve-maintained High-frequency, G. E. Bell, 814
Inductive Capacity in the Gaseous State, Cordonnier and Guinchant, 158
Indus Valley, Excavations in the, Sir John Marshall, 68
Industrial: Arts: The, their History, Development, and Practice as Educational Factors, F. J. Glass, 569; Psychology, Attitude of Employees to, A. Stephenson, 963: Research Laboratories: J. W. Williamson, 409; of the United States, including Consulting Research Laboratories, Third edition, compiled by C. J. West and E. L. Risher, 409
Industry, Education and, 45
Infantile Paralysis, Gift by J. Milbank for an International Research upon, 996
Inflammable Gas from Plants, F. C. Short, 172; W. A. Hamor, 283
Infra-red: Region of the Spectrum, Studies in the (1) (3) (4), Sir Robert Robertson and J. J. Fox; (2) Sir Robert Robertson, J. J. Fox, and E. S. Hiscocks, 1040; Solar Spectrum, Photography of the, H. D. Babcock, 830
Innsbruck University, Mrs. Ogilvie Gordon elected an honorary member of the, 996
Inositol, the Configuration of, S. and T. Posternak, 486
Inositotetraphosphoric Ester, A Natural Optically Active, S. and T. Poternak, 486
Insect: Collecting in the Southern Andes, F. W. Edwards, 265; Types, Prof. Graham Kerr, 882
Insects: and Potato Virus Diseases, K. M. Smith, 904; Embryology and Musculature of, L. Eastham; G. D. Morrison, 476; Fats of, The, J. Timon-David, 266
Insulating Oils, T. N. Riley and T. B. Scott, 478
Insulin: and Carbohydrate Metabolism, 260; and Synthalin, 151
Integration, The Theory of, L. C. Young, 54
Interferometer Pressure Gauge, On the Construction and Standardisation of an, J. J. Manley, 194
International: Botanical Congress, forthcoming, 394; Geographical Congress, forthcoming, 145; Geological Congress: forthcoming, 145; The Fifteenth, 720; Illumination Commission, forthcoming meeting of the, C. C. Paterson elected president, 547; Mathematical Congress, forthcoming, 145; Weights and Measures, 965
Intramolecular Transposition by Photochemical Action, Mme. Ramart-Lucas and F. Salmon-Legagneur, 229
Inventions, A Century of (James Forrest Lecture), Sir James Alfred Ewing, 947
Iodine: Bands, Optically Excited, with Alternate Missing Lines, Prof. R. W. Wood and Prof. F. W. Loomis, 283; The Absorption of, by Carbon in Some Organic Solvents, Trividic, 734; Vapour, The Action of Active Nitrogen on, L. H. Easson and R. W. Armour, 728
Ionisation: Incipient, Prof. J. Franck, 727; Potentials of Homologous Elements, Relationships between the, G. Piccardi, 229
Ionised Oxygen in the Gaseous Nebulæ, The Distribution of, J. H. Reynolds, 206
Ions in Crystals of Rare Earths, Polychroism and Orientation of the, R. Brunetti, 779
Ireland, Central and Southern, The Glacial Retreat from, Prof. J. K. Charlesworth, 438
Irish Family, A Short History of a Notable, P. C. Gallagher, 596
Iron: and Nickel at Low Temperatures, New Measurements of the Atomic Moments of, P. Weiss and R. Forrer, 733; and Steel Institute, presentation of the Bessemer gold medal to C. Schwab, 765; at Various Temperatures, Yield-point in, Prof. J. Muir, 338; Chromium-Carbon System, The, Westgren, Phragmén, and Negresco, 847; ‘Nitrides’ of, X-ray Studies on the, Dr. G. Hägg, 826; Ores of South Africa, Dr. P. A. Wagner, 964; Vitrium, and Lanthanum, Astrophysical Estimates of Ionisation Potentials of, A. V. Douglas, 906
Irregular Doublet Law, Extension of the, Prof. M. N. Saha, and P. K. Kichlu, 244
Italia: Flight of the, 684, 876; 916, 958, 994, 1028

Japanese Earthquake of 1923, The Origin of the, Prof. N. Yamasaki, 340
Java Citronella Oil, The Commercial Utilisation of, B. O'Donoghue, J. J. Drumm, and Prof. H. Ryan, 1042
Jibaros Indians, A Mummified Head (*tsantsa*) of the, E. Pittard, 486
Judex Analytical Reagents and Laboratory Chemicals, Catalogue of, 648
Juglans regia, Rotting of the Cultivated Walnut, and Calcium Carbonate, Gard, 971
Jupiter: A Photograph of, obtained at the Lick Observatory, California, Wright, 266; Observations of the Third Satellite of, G. Rougier, 158

K-rays of Aluminium, The Action of the, on some Micro-organisms, A. Lacassagne, 927
Kaolinite-bearing Nodules, Genesis of, S. Tomkeieff, 222
Katalyse mit kolloiden Metallen, W. Hückel, 317
Keeping Abreast—Some Aids for Physicists, Prof. J. A. Crowther, 162
Kent's Cavern, Sir Arthur Keith, 184
Kerr Effect, Disappearance and Reversal of the, Prof. C. V. Raman and S. C. Sirkar, 794
Kew, Royal Botanic Gardens, Popular Official Guide. Second edition, 825
Kinetic Theory, The, 492
King's Birthday Honours, The, 915
Kish, Archæological Work at, Prof. S. Langdon, 839
Kiwai Papuans of British New Guinea: a Nature-born Instance of Rousseau's Ideal Community, Prof. G. Landtman, 899
Kizaki Lake, Plankton in, The Diurnal Migration of, Dr. Kenzo Kikuchi, 480
Kostychev's Plant Respiration, Dr. S. Kostychev. Translated and edited by Prof. C. J. Lyon, 668
Kutta and Joukowski's Theorem: P. Straneo, 779; A Supposed Exception to, E. Pistolesi, 658

Labradorite from County Down, Ireland, The Optical Orientation of, determined by the Fedorov Method, W. Campbell Smith, 228
Lake Michigan Plankton, S. Eddy, 651
Laminaria, The Conditions of Release of Free Iodine in, P. Dangeard, 971
Lamps for Light-Baths, T. C. Angus, 639
Lancashire Coalfield, The, 651
Land: Drainage, 81; in England and Wales, Report of the Royal Commission on, 82; Tenure and Agricul-

tural Protection in the Tropics (being a Discussion on the Influence of the Land Policy on Development in Tropical Countries), Dr. H. Martin Leake, 89
Lapwings Act, The Protection of, 549
Larderello, Natural Steam Power Developments at, 59
Large Numbers, On the Law of, E. H. Linfoot, 969
Lathyrus, Linkage Groups and Chromosome Number in, Prof. R. C. Punnett, 157
Lead: Cable Sheathing, The Cracking of, S. Beckinsale and H. Waterhouse, 441, 922; Phosphate and Chlorophosphate (Pyromorphite), F. Zambonini and A. Ferrari, 1043; Qualities of, The Action of Small Additions of Tin and Cadmium on the, J. Cournot, 734; Separation and Determination of Small Amounts of, A New Method for the, B. S. Evans, 344; Tetra Ethyl: 362; Action of, in Delaying Detonation in the Internal Combustion Engine, Dr. E. Mardles, 424; in Internal Combustion Engines, H. S. Rowell, 570; Dr. E. Mardles, 571; Preparation of, T. Tanaka and T. Kuwata, 553; The Separation of, from Solution in Petroleum Spirit, F. W. Toms and C. P. Money, 814; The Use of, 594; in Motor Spirit, appointment of a Committee on, 549
Leadership, Science and, 233
Leeches on Fishes, D. H. Thompson, 599
Leeds University: Report for 1926–27, 731; bequest by F. C. Clayton; gift by Miss Florence Watts and sister; additional grant by the Clothworkers' Company, 887; Department of Textile Industries, Researches in the Colloidal Character of Wool, 120; Report on Adult Education Work, 691
Leidy, Joseph, Memorial Award, awarded to Dr. H. A. Pilsbry, 768
Leishmania tropica, The Exit of, through the Proboscis of *Phlebotomus papatasii*, Dr. S. Adler and O. Theodor, 282
Length, The Standard of, A. Pérard, 222
Lepidosiren paradoxa, The Sympathetic Nervous System of, Penelope M. Jenkin, 305
Leprosy, A New Remedy for, Sir Leonard Rogers, 331
Lethal Factors in a Grass, T. J. Jenkin, 1034
Lichens, Gonidia of, New Researches on the, O. Jaag, 657
Life, The Quest for, 978
Light: F. Bray, 237; V. T. Saunders, 237; and Sight, Sir John Parsons, 94; T. Smith, 242; Sir J. Herbert Parsons, 243; Dr. W. T. M. Forbes, 457; Prof. H. Hartridge, 616; Dr. F. W. Edridge-Green; T. Smith, 706; Curve of a Variable Star, A New Method for Determining the Form of the, G. Tiercy, 78; in a Wedge, The Interference of, F. L. Arnot, 405; -Quantum, The Impulse Moment of the, A. E. Ruark and H. C. Urey, 230; Scattering, A Change of Wave-length in, Prof. C. V. Raman, 619; at Critical Opalescence, Y. Rocard and M. Ponte, 746; by Individual Particles in Smokes, H. P. Walmsley, 193; Short Flashes of, Mechanical Production of, J. W. Beams, 863; The Emission of, by Flames containing Sodium and the Absorption of Light by Mercury Vapour, Prof. H. A. Wilson, 264; Therapy, The Physical Basis of, Prof. F. Ll. Hopwood, 625; -Year *versus* Parsec, Dr. H. D. Curtis, 789
Lighthouse Work, Gas-filled Lamps for, 473
Limnology, Recent Advances in, K. M. Strøm, 41
Line-integrals of the Diurnal Magnetic Variations, On, A. T. Price and Prof. S. Chapman, 969
Linnæus, The hundred and fiftieth anniversary of, 67
Linné à Jussieu, De: Méthodes de la classification et idée de série en botanique et en zoologie (1740–1790), Dr. H. Daudin, 85
Linnean Society of London: award of the Linnean gold medal to Prof. E. B. Wilson, 767; election of officers, 879; election of T. G. Halle, Prof. A. Harper, A. J. E. Lonnberg, T. W. Vaughan, and Prof. F. Zschokke, 805
Liquid: Stars: Dr. J. H. Jeans, 173, 279; Prof. A. S. Eddington, 278; and Atomic Volume, Prof. A. S. Eddington; Dr. J. H. Jeans, 496; Fuel from Coal, D. Brownlie, 645; Sulphur, The Temperature of Transformation of, into Viscous Sulphur, P. Mondain-Monval and P. Schneider, 694
Liquids: Constitution of, some New Experiments, Prof. H. B. Baker, 507
Liquorice Mass, The Examination of, P. Houseman, 814
Liver: Extract, B.D.H., British Drug Houses, Ltd., 877; Fluke: A Parasite of the Egg of the, Prof. J. B. Butler and J. J. C. Buckley, 185; Disease of Sheep, 686; in Pernicious Anæmia, 919
Liverpool University: impending conferment of honorary doctorates, 519; Twenty-fifth anniversary of the, 811
"Living: Matter," Structure and Development of the, Prof. F. Vejdovský, 610; Machinery: Six Lectures delivered before a 'Juvenile Auditory' at the Royal Institution, Christmas 1926, Prof. A. V. Hill, 314; Organisms, Intimate Association of, Prof. Doris Mac-Kinnon, 808
Livingstone College, 'Commemoration Day,' 1031
Lleyn (Carnarvonshire), The Pre-Cambrian Complex and Associated Rocks of South-western, C. A. Matley, with a chapter on the Petrology of the Complex, by E. Greenly, 483
Locomotion, Mechanical and Animal, Some Modes of, A. Mallock, 541
Locomotive-God, The, W. E. Leonard, 788
Locust Kernel Gum and Oil, A. L. Williams, 814
Locusts and Grasshoppers, B. P. Uvarov, 31
Logarithms and Anti-Logarithms, A Graphic Table Combining, A. Lacroix and C. L. Ragot, 276
London: and Londoners, 935; Mathematical Society: bequest to, by Lt.-Col. A. J. C. Cunningham, 840; Proceedings of the. Second edition. Vol. 26, 669; School of Hygiene and Tropical Medicine, large order of the, for microscopes to R. and J. Beck, Ltd., 596; The Earlier Inhabitants of, Prof. F. G. Parsons, 935; University: M. E. Delafield appointed professor of chemistry at the London School of Hygiene and Tropical Medicine; conferment of doctorates; Dr. E. L. Kennaway awarded the William Julius Mickle fellowship, 226; B. Ashmole appointed Yates professor of archæology; Prof. R. Robinson appointed professor of organic chemistry at University College, 402; conferment of doctorates, 430; new statutes for the, 445; award of Keddey Fletcher-Warr studentships to Dr. G. F. J. Temple and C. P. Snow, 481; the title of Prof. C. E. Spearman changed to that of professor of psychology; conferment of title of assistant professor of mechanical engineering on B. J. Lloyd-Evans; conferment of doctorates; award of the Petrie medal to Sir Aurel Stein, 519: Dr. W. W. Jameson appointed professor of public health at the London School of Hygiene and Tropical Medicine; Dr. E. E. Turner appointed reader in chemistry at Bedford College; conferment of the title of reader in physical chemistry on Dr. S. Sugden, 556; Report of the Principal, 812; Dr. C. B. Fawcett appointed professor of economic geography at University College; title of professor of experimental pathology conferred upon Dr. A. Leitch and that of reader in pathological chemistry upon Dr. C. R. Harington, 848; Dr. G. Hadfield appointed professor of pathology at the London School of Medicine for Women; Dr. P. Hartley appointed professor of biochemistry at the London School of Hygiene and Tropical Medicine, 848; conferment of the title of reader in physics on Miss M. O. Saltmarsh, 924; conferment of doctorates, 967, 1038; award of post-graduate travelling studentships to H. I. Andrews and D. M. Robinson, 1038; Sir Gregory Foster elected Vice-chancellor; Prof. Andrade appointed Quain professor of physics at University College, 1038; College, Annual Report, 887
Long Chain Compounds, The Structure of, E. Henderson, 965
Longitudinal Wave along a Rod, The, S. Ray, 733
Lotoflavin, etc., A Synthesis of, N. Cullinane, J. Algar, and Prof. H. Ryan, 1042
Loud Speaker, A new, 144
Loutreuil Foundation of the Paris Academy of Sciences, The, 119
Low Temperature Tar, The Constituents of, Prof. E. Bornstein, 356; Prof. G. T. Morgan and D. D. Pratt, 357
Lower: Carboniferous Rocks of the Menaian Region of Carnarvonshire, The, E. Greenly, 41; Jaw of Cattle, Movements of the, during Mastication, H. Riehm and E. A. Guggenheim, 357

Lubaantun, T. A. Joyce, C. Clark, and J. E. Thompson, 650
Lucretius, Prof. D'Arcy W. Thompson, 565
Lucretius's Anticipation of Mendelism, Prof. R. C. McLean, 749
Luminous Gas, Density of a, and the Emission of Light by Atoms in Metastable States, Prof. B. Venkatesachar, 356
Lunularia cruciata (L.) Dumortier, The Reproduction and Fungal Endophytism of, Theodora B. Auret, 890; The Life-history of, with Special Reference to the Archegoniophore and Sporophyte, W. T. Saxton, 345
Lury Vopo Vir Can Utriet, R. Steele, 208

Macacus rhesus, The Sensibility of, to the Virus of Yellow Fever, C. Mathis, A. W. Sellards, and J. Laigret, 559
Madras, Fisheries of, 887
Magdalenian Site, A, in the Dordogne, A. Viré and l'Abbé C. Teulière, 257
Magellanic Clouds, On the Motion of the, W. J. Luyten, 891
Magic Squares, Subsidiary Rectangles as applied to the Formation of, Major J. C. Burnett, 57, 172, 985
Magmatic Augite, Change of the Parameters of, A. Brun, 78
Magnesium and Zinc, The Constitution of the Alloys of, R. Chadwick, 441
Magnetic: Declination Tables for the Mining Industry, 999; Detection of Minerals, Dr. L. Palazzo, 258; Induction, D. Graffi, 607; Materials, Properties and Testing of, T. Spooner, 240; Measurements: W. J. Rooney; D. Stenquist, 601; in the Allier and the Puy-de-Dôme, E. Mathias, 851; in the East of France, Gibault and P. Rougerie, 559; Ocean Surveys, J. P. Ault, 473; Prospecting for the Detection of Faults in the Oligocene of Alsace, J. Jung and P. Geoffroy, 890; Rotatory Power, Research on the Thermal Variation of the, etc., H. Ollivier, 814; Storms and Sunspots, 842; Theory: Prof. D. M. Bose, 477; Prof. K. Honda, 552
Magnetism: and the Electro-Magnetic Field, 203; Applied, Dr. T. F. Wall, 240
Magneto Manual, The, H. R. Langman, 89
Maize, Genetic Effects of X-rays in, L. J. Stadler, 659
Malaria Commission of the League of Nations, Second General Report of the, 75
Malay: Life, Pathological and Normal, Primitive Instinctive Reactions in, Dr. F. H. G. Van Loon, 766; Peninsula: Commercial Timber Trees of the, Dr. F. W. Foxworthy, 1011; Ethnology and Archæology of the, Papers on the, I. H. N. Evans, 380; Resins and the Trade, H. Barry, 653
Malpighi, Marcello (1628-1694), T. E. James, 358
"Malta Fever", Proposed change of name for, 179
Maltese Cart-Ruts, The, Miss M. A. Murray, 297; Prof. Zammit, 599
Mammals and Man in the Transvaal, Prof. H. F. Osborn, 672
Mammoths and Man in the Transvaal, Dr. R. Broom, 324
Man: and Apes, The Evolution of, Prof. H. F. Osborn, 336; Early: and Civilisation, 567; Footprints of, D. A. Mackenzie, 567; God, and Immortality: Thoughts on Human Progress, Sir James George Frazer; revised and edited by the Author, 855
Manchester: Geological Association, *Journal* of the, No. 1, 216; University, Impending conferment of honorary doctorates, 402
Manitoba University, R. A. Wardle appointed professor of zoology in, 967
Mannar, Gulf of, Biology of the, Dr. F. H. Gravely, Dr. B. Sundara Raj, and others, 518
Mannocellulose, The Acetolysis of, G. Bertrand and J. Labarre, 158
Manual Dexterity, The Nature of, and its Relation to Vocational Testing, Prof. T. H. Pear, J. N. Langdon, and Edna M. Yates, 773
Maps: Early Engraved, Reproductions of, 1: The Map of the World on Mercator's Projection, by Jodocus Hondius, Amsterdam, 1608. With a Memoir by E. Heawood, 379; their History, Characteristics, and Uses: A Handbook for Teachers, Sir Herbert George Fordham. Second edition, 991
Marine: Algæ, The Release of Free Iodine in, P. Dangeard, 734; Biology in Ceylonese Waters, 261; Borers and their Relation to Marine Construction on the Pacific Coast, 832; Faunas of the Mediterranean and Red Seas, The Suez Canal in Relation to the, 249; Oil-Engines, Prof. C. J. Hawkes, 188
Marlborough College Natural History Society, Report of the, 189
Marmot Plague in U.S.A., 963
Marquesas Islands, The Geology of the, L. J. Chubb, 777
Mars and Jupiter, Conjunction of, 1032
Marsh Gas from Plants, Prof. A. Findlay, 58
Marshall Islanders' Charts, Sir Henry Lyons, 883
Martensite, Two kinds of, Prof. K. Honda and S. Sekito, 744
'Maté,' The *Sapécage* of, and the Presence of Ferments in *Ilex paraguariensis*, R. Chodat and A. Senglet, 694
Maternal Mortality, Circulars on, 769
Mathematical: Geography, Prof. A. H. Jameson and Prof. M. T. M. Ormsby. Vol. 1: Elementary Surveying and Map Projection, 277; Physics, Operational Methods in, Dr. H. Jeffreys, 451; Statistics, Prof. H. L. Rietz, 318
Mathematics: A Popular History of, 932; of Engineering, The, Prof. R. E. Root, 318
Mathématiques, Histoire des, W. W. Rouse Ball. Édition française revue et augmentée, traduite sur la troisième édition anglaise par Lieut. L. Freund. Tome 1, 932
Maya Cities: A Record of Exploration and Adventure in Middle America, Dr. T. Gann, 380
Mayas, The Ancient Astronomy of the, Dr. H. J. Spinden, 147
May-flies of India, The, Dr. B. Chopra, 551
Mechanical Quadratures, The Convergence of, in an Infinite Interval, J. Chokhate, 442
Mechanics: Theoretical Statics and the Dynamics of a Particle, Prof. W. D. MacMillan, 204
Medical: Education, Methods and Problems of, Series 8, 155; Research Council, Report of the, for the Year 1926-1927, 399; Trials, Some Famous, Dr. L. A. Parry, 241
Medicine, Experimental, An Introduction to the Study of, C. Bernard. Translated by H. C. Greene. With an Introduction by Prof. L. J. Henderson, 387; The Infancy of, an Enquiry into the Influence of Folk Lore upon the Evolution of Scientific Medicine, Dr. D. M'Kenzie, 133
Meifod, Montgomeryshire, The Geology of the District around, W. B. King, 889
Meiosis, Chromosomes in, Youngman, 844
Meldola Medal, presentation of the, to Dr. J. H. Quastel, 511
Mendelian Genes and Development, E. B. Ford and Prof. J. S. Huxley, 397
Mendelism, Lucretius's Anticipation of, Prof. R. C. McLean, 749
Mental Energy, Directing, Dr. F. Aveling, 168
Mercurous Chloride of Standard Purity, Luminescence of, Prof. J. Křepelka, 457
Mercury: and the Jovian Satellites, Observations of, M. Antoniadi, 183; Arc Converters, Large, 727; in Contact with Air, The Electro-Capillary Properties of, G. Colange, 266; Jets, Experiments with, and the Phenomena exhibited at their Impact with Steel and Glass, W. C. Baker, 814; -Thallium Molecule, Investigation of a, R. K. Waring, 675; The Band Spectrum of: Lord Rayleigh, 1042; excited by a High Frequency Discharge, J. G. Winans, 863; the Planet, W. F. Denning, 842; The Recent Transit of, Dr. B. Boss, 550; The Various Spectra of, M. Ponte, 606; Vapour, Fluorescence of, Prof. R. W. Wood and V. Voss, 418
Merseyside Aquarium Society, Annual Report and Proceedings of the, 32
Mersey Tunnel, New, Geological Features of the, Prof. P. G. H. Boswell, 970
Messel Medal of the Society of Chemical Industry, award of the, to Dr. R. A. Millikan, 334
Metal Films, Method of Preparing Thin, Dr. C. Mueller, 431
Metalix X-ray Tubes, Apparatus for use with, Watson and Sons (Electro-Medical), Ltd., 845

Metals: and Alloys, The Behaviour of, during Hot-forging, W. L. Kent, 442; Cold-working of, Density Charges caused by the, H. O'Neill, 442; Friction of, The Electromotive Force of, A. Lafay, 305; in Biological Material, Determination of Minute Quantities of, H. B. Taylor, part 1, 122; Institute of: *Journal* of the, Vol. 38, 825; Dr. W. Rosenhain elected president of the, 394; Passive, F. Kruger and E. Nähring, 222; Soft, and Eutectics, The Ball Hardness and the Cold-working of, F. Hargreaves, 442; The Photo-electric Properties of Some, in the Soft X-ray region, L. P. Davies, 1042
Metaphysics: and Modern Research, I. C. Isbyam. With Introduction and Introductory Essay: The Quest of Spiritual Truth, by L. Zangwill, 980; Physics and, W. W. L., 984
Meteor: Bright: from Halley's Comet, 769; on Feb. 3, W. F. Denning, 220; Large, on Jan, 9, W. F. Denning, 113; Showers of April and Early May, W. F. Denning, 725
Meteoric Display, A Probable, I. Yamamoto, 881
Meteorological Instruments, Catalogue of, C. F. Casella and Co., Ltd., 601
Meteorology, D. Brunt, 668; Correlation Coefficients in: E. V. Newnham, 421; Dr. R. A. Fisher, 712; Manual of, Sir Napier Shaw, with the assistance of Elaine Austin. Vol. 2: Comparative Meteorology, 931; World, Prof. V. Bjerknes, 931
Meteors: April Shower of, 649; and Skjellerup's Comet, W. F. Denning, 997; Bright, W. F. Denning, 147
Methane, The Molecular Structures of, J. K. Morse, 735
Methylene Blue, The Penetration of, into Living Cells, Matilda Moldenhauer Brooks, 346, 726; Dr. Marian Irwin, 939
Mexican Architecture of the Vice-Regal Period, W. H. Kilham, 168
Meyer, Frank N., Medal, presentation of the, to H. N. Ridley, 473
Micas containing Fluorine, The study of, by means of the X-rays, C. Mauguin and L. Graber, 851
Micro-Calorimeter, A, S. Lipsett, F. Johnson, and O. Maass, 1035
Microbes, Les, Prof. P. G. Charpentier. Avec un atlas de photomicrographies de P. Jeantet, 9
Microbial Antagonism and the Problem of Cancer, W. Arciszewski and W. Kopaczewski, 851
Microbiology, General, Laboratory Manual in. Third edition, 9
Microcline without macles, The Application of the Methods of Federow to the Identification of, M. Gysin, 657
Microcrescometer, The, Normal Type and Universal Type, S. C. Guha, 927
Micrograph, A New Reflex, Lt.-Col. J. V. Ramsden, 224
Microscope: A Pathological, R. and J. Beck, Ltd., 845; Projection Apparatus, Simple, J. F. Marshall, 687; Technique, T. Thorne Baker, 299
Mikrobiologie, theoretische, Vorlesungen uber, Prof. A. Rippel, 132
Mildew on Cotton Goods, G. Smith, 808
Milk, Fats of, Action of Cold on the, G. Quagliariello, 658; Pasteurisation and the Tubercle Bacillus, L. J. Meanwell, 513, 712; Sugar, The Synthesis of, A. Pictet and H. Vogel, 406
Milton and Modern Science, C. L. Barnes, 831
Mineral Colloids, Action of, on Normal and Syphilitic Blood Sera, R. Douris and J. Beck, 778
Minerals under the Microscope: The Determination of, with Special Reference to the Interpretation of Interference Phenomena, Dr. J. W. Evans, 980
Miners' Lamps, Prof. R. V. Wheeler and D. W. Woodhead, 223
Minimum Proper Time, On a, and its Application, Dr. H. T. Flint and Prof. O. W. Richardson, 264
Mining: and Metallurgy, Institution of: award of the gold medal of the, to Sir Alfred Mond, 549; presentation to, of a portrait of Dr. W. G. Miller, 916; presentation of the gold medal to Sir Alfred Mond, 917; Institute of Scotland, Jubilee of the, 878; Subsidence, The Reports of the Royal Commission on, C. H. Bailey, 179
Mississippi Floods, The, H. C. Frankenfield, 149
Mitochondria in the Germination of Cereals, Enzymatic Function of, E. S. Horning and A. H. K. Petrie, 157
Mnemotropism: Persistence tendency in Remembering, Dr. J. H. Kenneth, 423
Modernism: The Way of, and Other Essays, Rev. J. F. Bethune-Baker, 200
Modern Thought, 489
Mohenjo-daro, Sind, Prehistoric Animal Remains from the Ancient Indian City of, Major R. B. S. Sewell, 346
Mojave Desert, California, Late Tertiary Thrust Faults in the, D. F. Hewett, 658
Molecular: Dissymmetry dependent on Restricted Rotation about a Single Linking, W. H. Mills and K. A. C. Elliott, 78; Structure in Solution, O. R. Howell, 259; Transposition in the Cycloheptane Series, M. Godchot and Mlle. Cauquil, 443, 778; Velocities, Conditions of Excitation, and Probability of Transition in a Degenerating Gas, E. Persico (2), 779
Molybdenum: Additional Lines in the *K*-series of, and the Natural Breadth of Spectrum Lines, B. Davis and H. Purks, 735; Sulphides (1), N. Parravano and G. Malquori, 658; (2), N. Parravano and G. Malquori, 694
Monaco, La Grotte de l'Observatoire à, Prof. M. Boule et L. de Villeneuve; Les Poissons, les Batraciens, et les Reptiles dans l'art quaternaire, H. Breuil et Comte R. de Saint-Périer, 1012
Monomolecular Films, Dr. S. E. Sheppard and R. L. Keenan, 982
Mont-Revard, The Climatological Observatory of, d'Arsonval, Bordas, and Besson, 486
Moon, Colour Photography of the, F. J. Hargreaves, 997
Mosquito Surveys: A Handbook for Anti-Malarial and Anti-Mosquito Field Workers, M. E. Macgregor, 386
Mothers: The, A Study of the Origins of Sentiments and Institutions, R. Briffault, 3 Vols., 126
Motion: of a Runner exerting a Maximal Effort, The Equation of, C. H. Best and Ruth Partridge, 1005; Pictures, Talking and Synchronised, W. H. Bristol, 1029
Moulds, Development of, The Comparative Energy Yields of Various Glucides in, L. de Caro, 443
Mount Everest, Nature Notes from, Major R. W. G. Hingston, 344
Mouse, Gonads of the, Development and Morphology of the, part 2, Dr. F. W. R. Brambell, 157
Mucor spinosus (*Zygorhynchus spinocus*), Influence of Radium on the Production of the Zygospores in, A. and R. Sartory and J. Meyer, 814
Mucors, Sexes in, The Biochemical Differences between, Sophia Satina and A. F. Blakeslee (4), 890
Muller Hot Cathode Tube, Watson and Sons (Electro-Medical), Ltd., 1000
Müller-Pouillets Lehrbuch der Physik. Elfte Auflage. Herausgegeben von A. Eucken, O. Lummer, E. Waetzmann. In funf Banden. Band 5: Physik der Erde und des Kosmos (einschl. Relativitatstheorie). Zweite Halfte: Physik des Kosmos (einschl. Relativitatstheorie). Herausgegeben von A. Kopff, 824
Muscular Movement in Man: the Factors Governing Speed and Recovery from Fatigue, Prof. A. V. Hill, 314
Muscle: Cell, Rôle of Oxidation in Maintaining the Dynamic Equilibrium of the, Prof. A. V. Hill, 1005; Factors determining the Maximum Work and the Mechanical Efficiency of, Prof. A. V. Hill and W. Hartree, 1005; Twitch, The Absolute Value of the Isometric Heat Coefficient Tl/H in a, and the Effect of Stimulation and Fatigue, Prof. A. V. Hill, 1005; Twitches: The Absence of Delayed Anaerobic Heat in a Series of, Prof. A. V. Hill, 1005; The Recovery Heat-Production in Oxygen after a Series of, Prof. A. V. Hill, 1005
Mushrooms and Toadstools: An Account of the more common Edible and Poisonous Fungi of Canada, H. T. Gussow and W. S. Odell, 703
Music: The Effects of, a series of essays, edited by Dr. M. Schoen, 381
Mycetozoa, Sexuality in the, Wilson and Cadman, 999
Mycology, Academic, 742
Mycorrhizae, Biological Significance of, K. Masui; Prof. L. Knudsen, 114

Myothermic Apparatus, Prof. A. V. Hill, 1005
Mysterious Kundalini, The (the physical basis of the "Kundali (Hatha) Yoga," according to our present knowledge of Western anatomy and physiology), V. G. Rele, 4
Mystic Rose: The, A Study of Primitive Marriage and of Primitive Thought in its Bearing on Marriage, E. Crawley. New edition, revised and greatly enlarged by T. Besterman. 2 Vols., 126

Namaqualand, Artesian Water in the Gneiss Formation of, Dr. H. Merensky, 253
Naphthalene: Chlorination of, The, P. Ferrero and R. Wunenburger, 122; Derivatives. An X-ray Investigation of the Structure of some, J. M. Robertson, 969
National Physical: Laboratory, Report of the, 878; Research Council, Washington, Bulletin No. 59, 511
Natural: Capacity in the Population, The Distribution of, and the Need for a National Stocktaking, Dr. C. J. Bond, 291; Steam Power Developments at Larderello, 59
Nature: Interpreters of, Sir George Newman, 1016; Science and, St. G. Lane Fox Pitt, 748
Naturwissenschaften, exakten, Ergebnisse der. No. 6, 511
Naval Architects. Institution of, Lord Wester Wemyss invited to the presidency of the; award of premiums to H. J. R. Biles and W. C. S. Wigley, 334
Navy and Army, Health of the, Reports on the, 648
Neanderthal Man a Distinct Species, Prof. G. Elliot Smith, 141
Nebular Spectrum, The Density necessary to Produce the, Prof. D. H. Menzel, 618
Nebulium: and Hydrogen in New Stars, B. P. Gerasimovič, 422; Spectrum, The: Prof. J. C. McLennan and R. Ruedy, 319; in New Stars, The, C. T. Elvey, 453; S. R. Pike, 136; The Density necessary to produce the, C. T. Elvey, 12; The Origin of the, Prof. Meghnad Saha, 418
Negrito Racial Strain in India, B. S. Guha, 793
Nematode: Female, A Meristic Variation in a, C. H. Cassidy, 476; Spermatogenesis, N. A. Cobb, 552
Neon: The Density, Compressibility, and Atomic Weight of, G. P. Baxter and H. W. Starkweather, 659; The Spark Spectrum of, Prof. H. N. Russell, Prof. K. T. Compton, and J. C. Boyce, 357; the Viscosity of, The Effect of Temperature on, H. S. Edwards, 970; Tubes, New Type of Discharge in: F. A. Long, 1020; J. W. Ryde, L. Jacob, and B. S. Gossling, 794
Nepal, Survey of, 844
Neptune, Search for a Planet outside, Prof. W. H. Pickering, 598
Neurotic Personality, The, Dr. R. G. Gordon, 54
Newcastle-upon-Tyne, Sir Westcott Stile Abell recommended for appointment as professor of naval architecture at Armstrong College; H. P. Mulholland appointed lecturer in mathematics, 1038
New: South Wales: and Queensland, A New Dendrobium from, Rev. H. M. R. Rupp, 266; Basic Alkaline Rocks, Petrological Notes on some, W. R. Browne 122; Linnean Society of, Dr. W. R. Browne elected president of, 767; Vision, The, Prof. G. Elliot Smith, 680; Year Honours, 29; Year's Day: the Story of the Calendar, S. H. Hooke, 131; Zealand: Institute, election as honorary members of Dr. A. W. Hill and Sir John Russell, 595, 597; Scenery-Preservation, Report on, for 1926–27, 547; Scientific Periodicals in the Libraries of, *Reference List* of the, G. Archey, 509
Newton, Isaac, 1642–1727, A Memorial Volume edited by W. J. Greenstreet, 51
Newton's Library, Discovery of Books in, Col. de Villamil, 252
Nicholas Land, forthcoming expedition to, 255
Nichols medal of the New York section of the American Chemical Society, award of the, to Prof. H. S. Taylor, 292
Nickel: Electrolytic, Some Properties of, B. Bogitch, 158; Sulphide and Cobalt Sulphide in the Presence of Water, The Evolution of, Mlle. Suzanne Veil, 266; True Specific Heats of, Measurement of the, by a Direct Electrical Method, Mme. C. Lapp, 851
Nicotiana Species, The Production of Variation in, by X-ray Treatment of Sex Cells, T. H. Goodspeed and A. R. Olson, 659
Nicotine, New Synthesis of, E. Spath and H. Bretschneider, 601
Nierenstein Reaction, The, Dr. M. Nierenstein, 940
Nigeria: Southern, The Peoples of, a Sketch of their History, Ethnology, and Languages, with an Abstract of the 1921 Census, P. A. Talbot. 4 Vols., 975
Night Sky, The Light of the (3), Lord Rayleigh, 483
Nile: and Faiyum, The Relations of, in Pliocene and Pleistocene Times, Dr. K. S. Sandford and W. J. Arkell, 670; Floods, Periodicities in the, Dr. C. E. P. Brooks, 552, 850; Water Supply of the, Dr. H. E. Hurst, 34
Nitram, Ltd., The Activities of, 178
Nitrated Colouring Matters, The Action of Light upon, A. Seyewetz and D. Mounier, 42
Nitric: Acid, The Production of, from Atmospheric Nitrogen, Prof. Haber, 433; Oxide, The Action of, on the Thiosulphates of Metals of the Eighth Group (1), L. Cambi and Ada Clerici, 559
Nitrogen: Active: Dr. B. Lewis, 515, 864, 938; Dr. E. J. B. Willey, 149, 355; J. Kaplan and G. Cario, 906; P. K. Kichlu and D. P. Acharya, 982; J. Kaplan, 891; After-glow: A, Dr. S. P. McCallum and W. E. Perry, 942; The, Prof. J. C. McLennan, R. Ruedy, and J. M. Anderson, 537; Application of the Addition of, to certain Special Steels, L. Guillet, 889; Dioxide, Quantum Yield in the Photochemical Decomposition of, R. G. Dickinson and W. P. Baxter, 921; Fixation, Prof. G. Senn, 515; Peroxide: and Sulphur Dioxide, The Reactions between, E. Briner and G. Lunge, 406; The Absorption Spectrum of, L. C. K. Carvile, 298
Nitrogenous Substances of certain Types of Preserved Foods, The Nutritive Value of the, S. Baglioni and L. Settimj, 406
Nitrous and Nitric Oxides, The Photochemical Decomposition of, J. Y. Macdonald, 652
Nodal Cubic Surfaces, The, and the Surface from which they are Derived by Projection, G. Timms, 969
Noise: Harmful, Prof. J. J. B. Morgan, 396; The Economic Loss through the Effects of, Prof. H. J. Spooner, 110
Non-Colloidal Substances with Cryptotoxic Properties, H. Vincent, 889
Norfolk, Printed Maps of, A Descriptive List of the, 1574–1916: with Biographical Notes and a Tabular Index, T. Chubb. And a Descriptive List of Norwich Plans, 1541–1914, G. A. Stephen, 937
North: American: Diatoms, C. Boyer, 148; Indian Statistics, J. Mooney, 807; Shore Birds, A. C. Bent, 807; Terrestrial Isopods, H. Lomander, 33; County, Wicklow, The Waste Land of, S. Leonard, 1042; Sea, Rare Fishes in, Prof. E. Ehrenbaum, 709; -West America, Distributions in, R. L. Olson, 221
Northern Fayum Desert, Archæology of the, Miss G. Caton-Thompson, 683
Northumbrian Fault Block, Movements of the, H. C. Versey, 258
Nosema, Spore of, The Polar Filament of the, K. Ohshima, 257
Nottingham, University College, gifts by H. F. Lancashire and G. Spencer, 190
Nova Pictoris, 433, 649, 685; Dr. H. Spencer Jones, 545, 862, 962; Dr. Jackson, 806
Novaya Zemlya: Exploration in, Dr. R. Samoilovitch, 920; Microbiological Observations at, A. F. Kazansky, 650
Numbers, Theory of, The Present State of some Problems in the, Prof. L. J. Mordell, 138
Nutrition, Human, Problems in, 609

Observatories' Year Book, 1924, The, 668
Oceania, Model Houses over Graves in, P. Buxton, 770
Oceans, The Age of the, Prof. A. Holmes, 34
Œnothera: Flower, The 'outside in', G. H. Shull, 735; Linkage with crossing-over between *rubricalyx* buds and old-gold flower colour in, G. H. Shull, 735

Oersted, R. Appleyard, 877
Oil : and Gas at Bell Springs, Wyoming, C. E. Dobbin, H. W. Hoots, and C. H. Dane, 921 ; and Retortable Materials : A Handbook on the Utilisation of Coal, Torbanite, Cannel and Oil Shale, G. W. Halse, 201 ; Palm, Branching in the, M. T. Dawe, 435 ; The Separation of, from Condensation Water by Electrolysis, F. Hoyer, 515
Oilwells in Great Britain, Dr. A. Wade, 847
Old Red Sandstone of Scotland : The Flora of the, a General Survey, Prof. W. H. Lang, 485
Oldest of the Arts, The, and the Youngest of the Sciences, Dr. J. G. Myers, 274
Oldoway Skull, The, L. S. B. Leakey, 499
Olea laurifolia Lam. (Ironwood), Dr. J. F. V. Phillips, 42
Opal Glasses, The Analysis of, W. Singleton and R. C. Chirnside, 486
Ophthalmology, Recent Advances in, Dr. W. S. Duke-Elder, 1016
Optical : Cosine Law, An Extension of the, M. Herzberger, 305 ; Instruments for Research Laboratories and Works, Adam Hilger, Ltd., 1001 ; Paradox, An, T. Smith, 281 ; Dr. N. R. Campbell, Dr. L. F. Richardson, T. Smith, 536 ; J. W. Perry, 749 ; Phenomenon, A New, J. Cabannes, 889 ; Society, election of officers, 474
Optics, Studies in, Prof. A. A. Michelson, 237
Orang-utan, threatened extermination of the, 1028
Ordnance Survey, one-inch maps published 1801-1830, 768
Oriental Institute of the University of Chicago, Work of the, Prof. J. H. Breasted, 682
Ornithology, Economic, Dr. W. E. Collinge, 447
Orthacea, Rib-system in, On the Notational Representation of the, B. B. Bancroft, 442
Osmundaceæ, Sporangial Variation in the, S. Williams, 558
Ostrea, The Dominant Species of, Dr. J. H. Orton, 320
Ovarian Hormone, The, Dr. B. P. Wiesner, 498
Oversea Settlement Committee, Report of the, for the Year ended 31 Dec. 1927, 929
Oxford : English Dictionary, completion of the, 595 ; Old Ashmolean building, proposals for future use of the, 767 ; -Field expedition's excavations at Kish, The, Prof. S. Langdon, 180 ; University : The Bodleian Library ; Dr. F. A. Dixey elected to an emeritus fellowship, 100 ; leave of absence granted to Prof. G. H. Hardy ; Sir John Findlay, Bart. thanked for gift to the Lewis Evans Collection of Scientific Instruments, 226 ; Conferment of an honorary degree on Mrs. Florence Joy Weldon ; A research room to be added to Dr. Lee's department ; forthcoming expedition to Greenland, 262 ; gifts to the Lewis Evans Collection, 253 ; The Rouse Bell mathematical professorship ; J. P. Maxton appointed a research officer in the Agricultural Economics Research Institute ; Dr. T. V. Barker appointed secretary to the Curators of the University Chest, 342 ; Prof. H. H. Turner's Report on the University Observatory, 342 ; Report of the Bodleian Library, 439 ; Observatory. Annual Report, 475 ; proposed common room or club for members of the research or teaching staff of museum and other institutions, 481, 1003 : oration of E. Ll. Woodward on retirement as Senior Proctor, 519 ; Question of the extension of the Bodleian Library, 812 ; Viscount Grey of Fallodon elected Chancellor of the University ; Report of the University Museum, 1003 ; The Halley Lecture delivered by Dr. H. Shapley, 1038
Oxfordshire Flowers and the Plot Memorial Windows, Dr. G. C Druce, 93
Oxidation of Sulphites by Air, The, H. M. Mason and G. Walsh, 265
Oxide of Nitrogen, The Effect of Moisture on the Peroxidation of, E. Bruner and A. Van der Wijk, 78
Oxygen, Absorption of, on Charcoal, A. F. H. Ward and Dr. E. K. Rideal, 398 ; and Coal. The Reactions Between, W. Francis and R. V. Wheeler, 398 ; and Nitrogen, The Thermal Conductivities of, H. Gregory and S. Marshall, 193 ; in River Water, Diurnal Variation of, Butcher, Pentelow, and Woodley, 326
Oxygenation in Research, L. R. Cleveland, 998
Ozone in the Upper Atmosphere During the Year 1927, Measurement of the, H. Buisson, 890 ; layer of the Upper Atmosphere During the Night, The. D. Chalonge, 486 ; The Magnetic Behaviour of, O. R. Wulf, 230.

Pacific : Peoples and Problems of the, Dr. J. Macmillan Brown. 2 Vols., 665 ; The Petrology of the, Prof. A. Lacroix, 34
Paganism in the Churches, C. E. Lart, 843
Paint and Varnish, The Industrial and Artistic Technology of, A. H. Sabin. Third edition, 376
Paints and Varnishes, Technology of, Dr. L. A. Jordan, 376
Palæolithic : Implements of Sligo, The, J. Reid Moir, 57 ; Man, Studies of, Dr. G. M. Morant. II. A Biometric Study of Neanderthaloid Skulls and of their Relationships to Modern Racial Types, 141
Palæometrology, W. H. Matthews, 311
Palæontographical Society, annual meeting and election of officers, 724
Palæontologia Sinica. Ser. A, vol. 2, fasc. 1 : Palæozoic Plants from Central Shansi, Prof. T. G. Halle, 896
Palæontology and the Origin of Man (Romanes Lecture), Prof. D. M. S. Watson, 767
Palæo-pathology, A Unique Case of, N. Baudouin and Morel, 778
Palaobotanik, Handbuch der, Prof. M. Hirmer. Mit Beitragen von Dr. J. Pia und Dr. W. Troll. Band 1 : Thallophyta, Bryophyta, Pteridophyta, 564
Palestine, The Agricultural Problems of, Sir John Russell, 68
Paludina diluviana, On, V. Franz, 844
Panama Canal Zone, Flowering Plants of the, P. C. Standley. 919
Papuan Monograph, A, 899
Paraffins, Normal, at Different Pressures, The Boiling Points of the, Prof. S. Young, 522
Paraguayan Chaco, The Swamps of the, G. S. Carter, 850
Paramecium, Encystment of, L. R. Cleveland, 1033
Paramermis contorta, The Determination of Sex in, M. Caullery and Mlle. Marguerite Comas, 606
Parasitic Gastropod, A New, S. Hirase, 257
Paris Academy of Sciences : Prize awards of the, 74 : The Loutreuil Foundation of the, 119
Parthénogenèse, Les bases physiologiques de la fécondation et de la, A. Dalcq, 1010
α-Particle, The Ionisation Curve of an average, N. Feather and R. R. Nimmo. 405
Pascal : as a Man, F. S. Marvin, 449 ; Portrait of Mary Duclaux (A. Mary F. Robinson), 449
Passenger Pigeon, The Extinction of the, J. T. Waterhouse, 882
Passivity : and Protective Oxide Films, U. R. Evans, 351 ; The Theory of, W. J. Muller and K. Konopicky, 230
Pathology, The Principles of, Dr. C. P. White, 133
Peacock's 'Eye', The Colour of the, Lord Rayleigh, 827
Pearl Mussel, British Freshwater, Form Variations of the, H. H. Bloomer, 552
Peasants and Potters (The Corridors of Time, 3), H. Peake and Prof. H. J. Fleure, 375
Pelecypoda, New Carboniferous, J. W. Jackson, 397
Pellia Nessiana, The Chromosomes of, A. M. Showalter, 659
Pembroke College, Cambridge, Prof. A. Hutchinson elected Master of, 142
Pendulum Corrections, the Calculation of, G. Bigourdan, 926
Penrose gold medal of the Geological Society of America, awarded to Prof. T. C. Chamberlin, 219
Penrose's Annual : the Process Year Book and Review of the Graphic Arts. Edited by W. Gamble. Vol. 30, 133
Penzance Cable Station of the Western Union Telegraph Company, The, R. Appleyard, 767
Periodic System of Elements, Anomalous Groups in the, Prof. E. Fermi, 502
Periodicity. On, and its Existence in European Weather, Sir Gilbert T. Walker, 850

Perkin Medal, award of the, to Dr. R. E. Schmidt, 549; presented to Dr. I. Langmuir, 256

Petroleum, Base Exchange and the Formation of, Dr. M. Stuart, 940; Helium and the Genesis of, Prof. C. C. Farr and M. N. Rogers, 258; Tanks, The Protection from Lightning of, 549

Pharmacological Research in Great Britain, 689

Pharmacy and Allied Sciences, Quarterly Journal of, Part 1, 995

Phenolic Ethers with Ammosulphonic Acid, Sulphonation of, A. Quilico, 559

Philippine: House, Animal Life in a, Dr. F. X. Williams, 998; Sea-Urchins, Dr. T. Mortensen, 114

Phlebotomus, The North Chinese Species of the Genus, Prof. W. S. Patton and E. Hindle, 344

Phosphatic Fertilisers, 531

Phosphoric Acid: A New Indicator for the Volumetric Estimation of, L. Duparc and E. Rogovine, 694; Phosphates, and Phosphatic Fertilisers, W. H. Waggaman, assisted by H. W. Easterwood, 531; The Iodometric Estimation of, and the Use of Sodium Bicarbonate in Iodometry, P. Carré, 486

Phosphorus: Glow of, Spectrum of the, Dr. H. J. Emeléus and R. H. Purcell, 809; Spectra of, for Different Degrees of Ionisation, G. Déjardin, 158

Photochemical Clustering, Dr. B. Lewis, 792

Photoelectric: Cells, Red Sensitive, C. C. Paterson, 58; Photometer, A Simple Form of, Dr. J. H. J. Poole, 281; Threshold Frequency, The, and the Thermionic Work Function, R. H. Fowler, 264

Photoelectrons produced by X-rays, Spatial Distribution of, E. J. Williams, 134

Photogrammetry, The Principal Point and Principal Distance in, H. G. Bourcade, 42

Photographic: Blackening, The Laws of, Mlle. M. Hanot and H. Guillemet, 850; Image, Latent, The Mechanism of Formation of the, Dr. F. C. Toy, 865; Plate, The Law of Blackening of the, at Low Densities (3), E. A. Baker, 305; Stellar Photometry at Allegheny, 147

Photography: International Congress of, The Seventh, 111; The American Annual of, 1928. Vol. 42. Edited by F. R. Fraprie and E. J. Wall, 533

Photosynthesis, Prof. E. C. C. Baly, 218

Physical: and Optical Societies, Annual Exhibition of the, 117; Papers, Collected, Sir Jagadis Chunder Bose, 451; Science, General, Elementary, W. R. Jamieson, 495; Society, election of officers, election of Prof. A. Einstein as an honorary fellow, 684

Physico-Chemical Embryology, 1010

Physics: and Metaphysics, W. W. L., 984; A Short History of, H. Buckley, 823; Classified Problems in, Part 1: Mechanics and Hydrostatics, D. B. Briggs and M. Briggs: Part 2: Magnetism and Electricity, D. M. Briggs; Part 3: Heat, Light and Sound, D. B. Briggs, 388; for Colleges, Prof. H. H. Sheldon, Prof. C. V. Kent, Prof. C. W. Miller, and Prof. R. F. Paton, 237; for School Certificate (Heat, Light and Sound): a Revision Course, W. Littler, 417; for Students, Prof. H. S. Allen, 237; in Astronomy, Sir Frank Dyson, 839; in Medical Radiology, Prof. S. Russ, Dr. L. H. Clark and B. D. H. Watters, 569; Institute of, Report of the, election of officers, 838; Modern, 316; Some Aspects of, Prof. A. Ogg, 880; The Logic of, Prof. P. W. Bridgman, 86; The Validity of, Dr. H. Jeffreys, 86; The Elements of, Prof. A. W. Smith. Second edition, 237; Theoretical, Research Progress in, H. F. Biggs, 503

Physik, Handbuch der, Herausgegeben von H. Geiger und K. Scheel: Band 23: Quanten, Redigiert von H. Geiger, 7; Band 15: Magnetismus; Elektromagnetisches Feld, Redigiert von W. Westphal, 203; Band 24; Negative und positive Strahlen, zusammenhängende Materie, Prof. H. Geiger, 414; Lehrbuch der, Prof. T. Wulf, 316

Physiological Society, History of the, during its First Fifty Years, 1876-1926, Sir Edward Sharpey-Schafer, 491

Physiology in Great Britain, 491

Picea excelsa, The Biological Study of, J. Costantin, 693

Pickering, the late Spencer, F.R.S., The Scientific Work of, Prof. T. M. Lowry and Sir John Russell. With a biographical notice by Prof. A. Harden, 48

Pickett-Thomson Research Laboratory, Annals of the, Vol. 3 (containing a historical survey of researches on the Streptococci), 701

Pieris napi L., Induced Changes in the Pigmentation of the Pupae of, and their Inheritance, Prof. J. W. H. Harrison, 157

Pike, A Voracious, Sir Herbert Maxwell, Bart. 908

Pinus insignis (*P. radiata*), Some Mechanical Properties of Australian-grown, with notes on the wood structure, M. B. Welch, 122

Pitman's Dictionary of Industrial Administration, edited by J. Lee. Part 1, 389

Pit River Indian Tribes, California, F. B. Kniffen, 770

Plague: in India, The Yearly Variations in, in relation to Climate: Forecasting Epidemics, Sir Leonard Rogers, 344; in Shakespeare's London, The, F. P. Wilson, 368

Plaice-egg Production in 1920-21, treated as a Statistical Problem, with comparison between the data from 1911, 1914, and 1921, H. J. Buchanan-Woolaston, 416

Planetary Photography, Prof. W. H. Wright, 962

Planets, Minor Discovery of, 962

Plankton Migrations, 480

Plant: Cell during Leaching Experiments, The Maintenance of Semi-permeability in the, F. C. Stewart, 523; Cells, Long-lived, D. T. MacDougall and others, 844; Diseases, The Control of, Mrs. N. L. Alcock and others, 153; Lice, The, or Aphididae of Great Britain, F. V. Theobald, Vol. 2, 386; The, as a Sensitive Structure, Sir J. C. Bose, 994; Tissues, The Influence of Temperature on the Responses of, to Electrical Stimulation, Prof. H. H. Dixon and T. A. B. Clark, 693; World, Development of the, A Critical Period in the, Prof. A. C. Seward, 896

Plants of the Past: A Popular Account of Fossil Plants, Dr. F. H. Knowlton, 788

Platinum: Alloys in Thermionic Valves, J. E. Harris, 884; Colloidal, Constitution of, S. W. Pennycuick, 35; in Sierra Leone, Discovery of, 70

Pleochroic Haloes and the Age of the Earth, Dr. F. Lotze, 90; Prof. J. Joly, 207

Plumage and Sexual Development, Dr. G. J. van Oort, 770

Poisonous Plants of the Farm, H. C. Long, 510

Poisons exciting the Nervous Centres, Physiological Doctrine of the Action of, S. Baglioni, 606

Polarisation: Colour Scheme, A, Drs. W. R. Jones and A. Brammall, 259; of Impact Radiation, On the Quantum Theory of the, J. R. Oppenheimer, 346

Pollution, The Effect of, on the Ecology of a Small Stream, R. W. Butcher and F. T. K. Pentelow, 656

Polychaeta, Prof. W. B. Benham (British Museum (Natural History); British Antarctic (Terra Nova) Expedition, 1910, Natural History Report, Zoology, Vol. 7, No. 2), 856

Polyhydric Alcohols, The Oxidation of some, by Periodic Acid, L. Malaprade, 443

Polyploid Plants, Production of, C. A. Jorgensen, 513

Polyporus, the Birch, Influence exerted by the Support on the Morphological Characters of, L. Lutz, 890

Polystomella crispa (Linn.), On the Further Researches of Joseph Jackson Lister upon the Reproductive Processes of, E. Heron-Allen, 441

Polyzoa from the Adriatic and Mediterranean, Dr. A. Neviani, 396

Pons-Winnecke Comet (1927 c), Polarimetric Observations of the, A. Danjon, 1006

Poona, The New Meteorological Observatory at, 108

Port Erin, Research Work at, 297

Portuguese Mineral Waters: Spectro-Chemistry of the: The Waters of Geres, A. P. Forjaz, 971

Positive Ion Kinetics, G. P. Harnwell, 808

Possible Worlds, and other essays, J. B. S. Haldane, 785

Post Office Underground Electric Railway, Completion of the, 254

Posture, The Effect of, upon the Composition and Volume of the Blood in Man, W. O. Thompson, Phebe K. Thompson, and Mary Elizabeth Dailey, 659

Potarite, A New Mineral discovered by the late Sir John Harrison in British Guiana, Dr. L. J. Spencer, 228

Potassium : Alum-hydrochloric Acid Solutions, The Effect of, on the Growth and Fate of Neoplastic Tissue (2), L. C. Strong, 346 ; Effect of, on Invertebrate Muscle, G. P. Wells, 1033 ; Molecule, The Photo-electric Threshold and the Heat of Dissociation of the, R. W. Ditchburn, 521 ; Rubidium, and Cæsium Sulphates, The Space Group of, F. P. Goeder, 346 ; The Intensity of the Lines of the Principal Series of, F. Rasetti, 559
Potato : Disease, The Phenomena of Necrosis in, Tsen-Cheng, 657 ; Virus Diseases, Insects and, K. M. Smith, 904
Povaze věci, O, Sir William Bragg. Přeložili Prof. A. Šimek a Dr. Hannah Šimkova-Kádlcová, 495
Power Alcohol in Australia, Prof. J. Read, 175
p-oxytriphenylcarbinol and *p*-oxydiphenylmethane under pressure, The Catalytic Hydrogenation of, W. Ipatief and B. Dolgof, 158
Pozzolanas, 515
Praseodymium and Neodymium, The Resolution of an Absorption Band regarded as Common to, L. Fernandes, 406
Prehistoric : Cave Art, Miss D. A. E. Garrod, 180 ; Research in France, M. C. Burkitt, 1012
Prices of Periodic Scientific Publications, Dr. Baini Prashad, 499 ; W. Bonser, 588 ; F. C. Nicholson, 749
Priests and Kings (The Corridors of Time, 4), H. Peake and Prof. H. J. Fleure, 375
Primary Production, Science and, R. H. Cambage, 225
Primitive Marriage and Kinship, Prof. B. Malinowski, 126
Procyon, The System of, Dr. Spencer Jones, 881
Projective Tensors and Connections, O. Veblen, 735
Proteins, Biological Functions of the, Dr. Dorothy Jordan Lloyd, 883
Protons in Metals, Prof. A. Coehn, 687
Protophyta, Parallel Evolution among, Prof. F. E. Fritsch, 62
Protura, British Species of, H. Womersley, 998
Pseudorca crassidens, False Killer-whales, in the Dornoch Firth, M. A. C. Hinton, 441
Psychiatry, Manual of, edited by Dr. A. J. Rosanoff. Sixth edition, 382
Psychology : An Introduction to, Prof. J. J. B. Morgan and Prof. A. R. Gilliland, 89 ; and the Soldier, F. C. Bartlett, 89 ; International Congress of, Officers of the Ninth, 474 ; Studies in, Memory, Emotion, Consciousness, Sleep, Dreams, and allied Mental Phenomena, Dr. W. Elder, 318
Psycho-Pathology : Its Development and its Place in Medicine, Dr. B. Hart, 378 ; Problems in, Dr. T. W. Mitchell, 277
Psygmophyllum Gilkineti, nov. sp., from the Middle Devonian (with old Red Sandstone facies) of Malonne, Belgium, Suzanne Leclercq and M. Bellière, 122
Ptolémée, Claude, Composition mathématique de, Traduite par M. Halma, et suivie des notes de M. Delambre, Tomes 1 et 2, 822
Ptolemy, The Almagest of, 822
Pure Rivers Society, Annual Report of the, 430
Pyknometer for Specific Gravity Determination, A Simple and Accurate Constant-volume, H. V. Ellsworth, 228
Pyrazolines, Oxidation of the, The Mechanism of the, R. Locquin and R. Heilmann, 158
Pyrophoric Lead, G. R. Levi and A. Celeri, 1043

Quadrics of Riemannian Space of Three Dimensions, G. Burani, 1043
Qualitative Analysis, A Rapid Method of, G. Gutzeit, 927
Quanta : 7 ; Theories of, Prof. G. P. Thomson, 977
Quantum : and Relativity Theories of Light, The, Prof. E. T. Whittaker, 471 ; Postulate, The : and Atomic Theory, F. J. Selby, 828 ; and the Recent Development of Atomic Theory, Prof. N. Bohr, 78, 580 ; The, and its Interpretation, Prof. H. S. Allen, 977 ; Theory : New Problems in, 579 ; of Quasi-Unimolecular Gas Reactions, The, O. K. Rice, 735 ; of the Electron, The, P. A. M. Dirac, 264
Quartz : Resonators, G. W. N. Cobbold and A. E. Underdown, 436 ; The Electro-optical Theory of, R. de Mallemann, 783
Quaternary : Human Skeletons from the Vallée du Roc, Charente, Dr. H. Martin, 963 ; Quadratic Complex, The Invariant Theory of the, Part 1, Prof. H. W. Turnbull, 41
Queensland, Report of the Land Settlement Advisory Board on the Wool Industry of, 109
Quekett Microscopical Club : election of E. M. Nelson, Dr. A. Mann, and Dr. K. Viets as honorary members, 111 ; election of officers, 295
Quenching and Tempering Non-ferrous Alloys, The Effect of, T. Matsuda and A. L. Norbury, 728
Quinine, Eserine, Pilocarpine, Digitonine, Sparteine, and Atropine, Action of, on the Nervous Centres, S. Baglioni, 606
Quinite, Some Derivatives of, L. Palfray and B. Rothstein, 814
Quinone, A Synthesis of, J. F. Durand, 890

Rabies, Elimination of the Virus of, by the Digestive Tract, V. Puntoni, 230
Radial Velocities of η-Aquilæ, Y Ophiuchi and X Cygni, The Variations of the, G. Tiercy, 122
Radiation and Electrons, The Interaction between, Prof. A. H. Compton, 337
Radiations, The Photobiological Action of, J. Risler, A. Philibert, and J. Courtier, 851
Radio : Beam Services, The Progress of, 31 ; Broadcast Signals, Variations of, Prof. E. V. Appleton, 652 ; Broadcasting Stations, Design and Distribution of, Capt. P. P. Eckersley, 218 ; -Elements as Indicators : and other Selected Topics in Inorganic Chemistry, Prof. F. Paneth, 1015 ; Photogram Service between London and New York, Extension of the, 1031 ; Wave-lengths, The International Radio Communication Conference and, 430 ; Waves : Polarisation of, J. Hollingworth and R. Naismith, 171 ; J. Hollingworth, 1040
Radioaktivitat, Prof. S. Meyer and Prof. E. Schweidler. Zweite Auflage, 162
Radioelectric Direction Finding, A Method of, applicable to Geodesy, P. Schwartz, 266
Radiologie, Handbuch der, Herausgegeben von Prof. E. Marx. Zweite Auflage. Vierter Band, Dritter Teil : Glühelektroden, von Prof. O. W. Richardson, ubersetzt und bearbeitet von Prof. A. Karolus ; Technische Anwendung der Gluhelektroden, von Prof. H. Rukop ; Flammenleitung, von Prof. E. Marx, 1014
Radiology, British Institute of, election of officers, 879
Radiotelegraphic Waves, The Velocity of Propagation of, A. Lambert, 657
Radium : -C, Thorium-C and -C′, The Redetermination of the Velocities of Particles from, G. H. Briggs, 404 ; E, The Disintegration of, from the point of view of Wave Mechanics, Prof. G. P. Thomson, 615
Raffles College, Singapore, Dr. R. K. Butchart appointed professor of mathematics at, 262
Railway Electrification : F. Lydall, 727 ; Automatic Substations in, H. B. Poynder, 477
Rain : over the British Isles, The Frequency of, Dr. J. Glasspoole, 591 ; The Distribution over the British Isles of the Average Number of Days with, during each Month of the Year, Dr. J. Glasspoole, 405
Rainbow Visible after Sunset, B. M. Peek, 985
Rainfall : and Flow-off : River Garry, Inverness-shire, Capt. W. N. McClean, 37 ; The Relation between, R. Corless, 37 ; British, 1926, 88 ; Interception by Plants, Dr. J. Phillips, 354 ; Law, A Simple, H. Jameson, 170
Ramsay : Fellowships, appointments to, 155 ; Laboratory of Chemical Engineering at University College, gifts for the, 556
Rana temporaria : Action of Guanidine on the Melanophores of the Skin of, S. Ochoa, 157 ; The Urinogenital Organs of the Male Frog, J. H. Lloyd, 423
Rare : Earth : Elements in the Periodic System, The Position of the, Prof. J. F. Spencer, 728 ; Materials and Element No. 72, W. B. Holton and B. S. Hopkins, 514 ; Metals, Determination and Separation of, from other Metals, (10), L. Moser and J. Singer, 230

Rasa-Jala-Nidhi: or Ocean of Indian Chemistry and Alchemy, Rasacharya Kaviraj Bhudeb Mookerji. With English translation by the Author. Vol. 2, 793
Rats: and How to Kill them, A. Moore Hogarth, 597; etc., the Rodier method for the extermination of, 30
Ray Society, election of officers, 511
Rayleigh Wave Problem, A, R. Stonely, 522
Rayleigh's Principle as applied to Continuous Systems, The Theory of, G. Temple, 1041
Rayon Industry, The, M. H. Avram, 739
Reaction, The Reversibility of a, Produced by a Spark or by the Electric Current, P. Jolibois, H. Lefebvre, and P. Montagne, 778
Reason, The Age of, Sir Philip Gibbs, 895
Red: Crystals appearing, under the Influence of Cresyl Blue, in the Cells of certain Algæ, The Signification of, G. Mangenot, 266: Sea, The Tides of the, Mme. E. Chandon, 657
Reducing Sugar containing Seven Atoms of Carbon, The preparation, by the Sorbose Bacterium, of a New, G. Bertrand and G. Nitzberg, 777
Reflecting Prisms, The Design of, T. Y. Baker, 41
Reflex Postural Adjustments of Balance in the Duck, Prof. D. Noël Paton, 305
Regeneration and Transplantation, Prof. E. Korschelt. Band 1: Regeneration, 825
Regional Survey, Miss C. Pugh and G. E. Hutchings, 687
Registrar-General's Provisional Report, The, 182
Reichert Microscopes and Accessories, 186
Reindeer in Norway, Extermination of, C. Schulz, 145
Relativistic Quantum Theory, The Fifth Dimension in, N. Wiener and D. J. Struik, 891
Relativity: and Wave Mechanics, W. Wilson, 483; The Mathematical Theory of, Prof. T. de Donder, 979
Religious Conversion: a Bio-Psychological Study, Prof. S. De Sanctis. Translated by Helen Augur, 824
Renal: Disease, Diagnosis and Treatment of, Modern Methods in the, Prof. H. MacLean. Third edition, 383; Function, The Alterations in the, by Hypochlorination, L. Blum and P. Graber, 306
Research and Development in Australia, 427
'Reversion,' 'Sports' and, Prof. M. Drummond; The Writer of the Notes, 575

REVIEWS AND OUR BOOKSHELF.

Agriculture, Forestry, and Horticulture:

Agricultural Progress, 1009
Ashley (Sir William), The Bread of our Forefathers: an Inquiry in Economic History, 858
Bennett (H. H.), and R. V. Allison, The Soils of Cuba, 859
Comber (Prof. N. M.), An Introduction to the Scientific Study of the Soil, 167
Davy (J. Burtt), and L. Chalk, The Collection and Preparation of Herbarium and Timber Specimens, 788
Foxworthy (Dr. F. W.), Commercial Timber Trees of the Malay Peninsula, 1011
Howard (A.), and Gabrielle L. C. Howard, The Development of Indian Agriculture, 698
Leake (Dr. H. M.), Land Tenure and Agricultural Production in the Tropics: being a discussion on the Influence of the Land Policy on Development in Tropical Countries, 89
Matthews (R. Borlase), Electro-Farming: or the Application of Electricity to Agriculture, 742
Royal Botanic Gardens, Kew. Popular Official Guide. Second Edition, 825
Weaver (Prof. J. E.), and W. E. Bruner, Root Development of Vegetable Crops, 58

Anthropology and Archæology:

Allcroft (A. H.), The Circle and the Cross: a Study in Continuity. In 2 Vols. Vol. 1: The Circle, 743
Blackman (Winifred S.), The Fellāhīn of Upper Egypt: their Religious, Social, and Industrial Life of To-day, with special reference to Survivals from Ancient Times, 380
Boule (Prof. M.), et L. de Villeneuve, La Grotte de l'Observatoire à Monaco (Archives de l'Institut de Paléontologie humaine, Mémoire 1), 1012
Breuil (H.), et Comte R. de Saint-Périer, Les Poissons, les Batraciens et les Reptiles dans l'Art quaternaire (Archives de l'Institut de Paléontologie humaine, Mémoire 2), 1012
Briffault (R.), The Mothers: a Study of the Origins of Sentiments and Institutions. 3 Vols., 126
Brown (Dr. J. Macmillan), Peoples and Problems of the Pacific. 2 Vols., 665
Crawley (E.), New edition revised and enlarged by T. Besterman. The Mystic Rose: a Study of Primitive Marriage and of Primitive Thought in its bearing on Marriage. 2 Vols., 126
Evans (I. H. N.), Papers on the Ethnology and Archæology of the Malay Peninsula, 380
Frazer (Sir James George), Man, God, and Immortality: Thoughts on Human Progress, 855
Gann (Dr. T.), Maya Cities: a Record of Exploration and Adventure in Middle America, 380
Gompertz (Dr. M.), Corn from Egypt: the Beginning of Agriculture, 131
Home (G.), Roman Britain, 241
Hooke (S. H.), New Year's Day: the Story of the Calendar, 131
Kaudern (Dr. W.), Ethnographical Studies in Celebes. Results of the Author's Expedition to Celebes, 1917–1920. Vol. 3: Musical Instruments in Celebes, 277
Kendrick (T. D.), The Druids: a Story in Keltic Prehistory, 204
Landtman (Prof. G.), The Kiwai Papuans of British New Guinea: a Nature-Born Instance of Rousseau's Ideal Community, 899

Penrose's Annual: the Process Year-Book and Review of the Graphic Arts, Vol. 30. Edited by W. Gamble, 133
Roberts (J.), Coal Carbonisation, High and Low Temperature: a Treatise on the Principles and Processes of Manufacturing Coke and Semi-Coke, 201
Sorbin (A. H.), The Industrial and Artistic Technology of Paint and Varnish. Third edition, 376
Wheeler (E.), The Manufacture of Artificial Silk: with special reference to the Viscose Process, 739

Rice, Colour Varieties of, Mitra, Gupta, and Ganguli, 920
Riechstoffe und ihre Herstellung, Synthetische und isolierte, Dr. R. Knoll. Zweite Auflage, A. Wagner, 568
'Rigor from Thawing,' Production of Lactic Acid and of Phosphoric Acid in, L. De Caro, 607
Ripples, Some Acoustical Phenomena Illustrated by, A. H. Davis, 305
Road Tar Extracts, Toxic Effects of, on Trout, A. C. Gardiner, 33
Roads, The Story of the, C. H. Hartmann, 860
Rock: Metamorphism, Some Factors in, D. White, 658; -Salt Lattice, Existence of Zero-point Energy in the, by an X-ray Diffraction Method, R. W. James, I. Waller, and D. R. Hartree, 192
Roe Deer, Unusual Gestation of, Dr. J. Ritchie, 882
Roman: Britain, G. Home, 241; Copper 'Soldering' and Welding from Uriconium, An Example of, Dr. J. Newton Friend and W. E. Thorneycroft, 484
Romanes Lecture, The, Prof. D. M. S. Watson, 767
Romani Versions, Sir Donald Macalister, 901
Root Development of Vegetable Crops, Prof. J. E. Weaver and W. E. Bruner, 53
Rosewood (*Dysoxylon Fraseranum*), The Essential Oil from the Timber of, A. R. Penfold, 122
Rotation and Geodesy, The Heterogeneous Fluid Mass in, R. Wavre, 78
Rotatory and Refractive Dispersion, Natural, M. L. Pagliarulo, 79
Royal: Academy Exhibition, 764; of Belgium, Sir Ernest Rutherford and Prof. J. Perrin elected associates of the, 917; Anthropological Institute, Prof. J. L. Myres elected president, 182; Astronomical Society: award of the gold medal to Prof. R. A. Sampson, the Jackson-Gwilt bronze medal to Dr. W. H. Steavenson, and to W. Reid, 111; election of officers, 255; Botanic Gardens, Kew, Picture Postcards of the, 294; College of Veterinary Surgeons, Sir John McFadyean awarded the diploma of honorary associate of the, 143; Geographical Society: awards of the, 722; offer of a flag by Capt. Wilkins, 805; E. A. Reeves awarded the Victoria medal, 917; Institute of British Architects, Principal A. P. Laurie and N. Heaton elected honorary associates of the, 255; Institution, election of officers, 768; Meteorological Society, election of officers, 146; Microscopical Society, election of officers, 146; Observatory, Greenwich, Annual Visitation of the, Dr. A. C. D. Crommelin, 923; Photographic Society, award of the Progress medal to Dr. S. E. Sheppard, 109; Society: election, selected candidates, 300; Conversazione, The, 846; elections to the, 1036; of Arts, award of the Albert medal to Sir Ernest Rutherford, 996; of Edinburgh, election of fellows, 394; award of the Keith prize to Prof. T. J. Jehu and R. M. Craig, and the Bruce prize to Prof. H. U. Sverdrup, 961
Rubber Latex, A New Injection Mass, Dr. R. R. Burt, 497
Rubrene: Researches on, C. Moureu, C. Dufraisse, and L. Girard, 850; (7), 889
Russian: Academy of Sciences, The, and its Institutions, 437; Fisheries Research in the Pacific Ocean, 882; Zoological Studies, 551
Rutherford's Theory of the Satellites, G. Gentile, 1043
Ruthless Republic, A, 166
Ruth's Steam Accumulator, A. J. T. Taylor, 845
Rydberg Term Tables, Prof. Paschen and others, 920

Saccharose, The Photolytic Action on Pure, of the Total or Filtered Radiations of the Mercury Arc, A. Andant and E. Rousseau, 442
Sagitta, S. T. Burfield, 385
Saha Theory, The, and the Conductivity of Flames containing Alkali Metal Vapours, H. A. Wilson, 404
St. Andrews: and Loch Leven: Igneous Intrusions between, F. Walker and J. Irving, 889; University: gift by Dr. D. Russell for a scholarship, 556; proposed conferment of honorary doctorates on Prof. E. P. Cathcart and Prof. W. Darrach, 604; A. R. Knight to be appointed to a lectureship in philosophy; Dr. F. Bath appointed lecturer in mathematics, 775
St. Kilda, Survey of, J. Mathieson, 514
St. Lawrence Earthquake of Feb. 28, 1925, The, E. A. Hodgson, 727
Salicylates and Cinchophen in Medicine, Actions and Uses of the, Prof. P. J. Hanzlik, 382
Salmon: from the River Shannon, 1924, 1925, and 1926, R. Southern, 485; Land-locked, C. Tate Regan, 502; Migration of the, The Influence of a Power Dam in Modifying Conditions affecting the, H. B. Ward, 846; The Interruption of the Movement of, up Rivers by the Reduction of the amount of Dissolved Oxygen in the Water Course, Chevey, L. Roule, and Mlle. Verrier, 159
Salt: Crystals as Nuclei of Sea Fog Particles, Sir Napier Shaw, 866; Dome in the Plain of Alsace, The Discovery, near Hettenschlag, of a Second, C. and M. Schlumberger, 486; Uncommon Common, A. F. Dufton and C. G. Webb, 942
Salting-out Effect, The, J. S. Carter and R. K. Hardy, 436
Samoa, The Insects of, 964
Sands, Catalogue of, A. L. Curtis, 512

Sap in Trees, Ascent of, Dr. D. T. MacDougal, Prof. J. B. Overton, and Prof. G. M. Smith, 185
Sapporo Agricultural College, Fiftieth Anniversary of the, 76
Scenery, The Science of, 309
Schist Geology: Braemar, Glen Clunie, and Glen Shee, E. B. Bailey, 522
Schizopepon Fargesii, a New Plant containing Maltose, H. Colin and R. Franquet, 734
School Natural History, 189
Sciara (Diptera), Genetic Evidence of a Selective Segregation of Chromosomes in a Second Species of, C. R. Metz, 735
Science: and Faith, 448; and Leadership, 233; and Nature: Dr. J. E. Turner, 617; St. G. Lane Fox Pitt, 749; and Policy in India, Major A. G. Church, 698; and Primary Production, R. H. Cambage, 225; and the Civil Service, Prof. J. C. McLennan, 643; and the Humanities, The Relationship between, Sir Richard Gregory, 118; and Theology, Rev. J. C. Hardwick, 200; Contributions of, to Religion, Rev. Shailer Mathews and others, 200; Elementary General, J. B. Jenkins, First and Second Year's Courses, 388; Masters' Association, Annual Meeting of the, 118; election of Prof. A. C. Seward as president, 119; Museum: Heirlooms of Industry in the, Col. Sir Henry G. Lyons, 1024; The New Buildings of the, 109, 458; Teaching in England, History of, D. M. Turner, 125; in Schools: E. Nightingale; A. K. Goard, 453; F. S. Young; H. E. A., 454; A. K. Goard; R. Weatherall, 572
Scientific: and Industrial Research, Report on, for 1926–1927, 554; and Learned Societies of Great Britain and Ireland, The Year-Book of the, Forty-fourth annual issue, 748; and Technical Books, Recent: Jan. 28, Suppt., v.; Feb. 25, Suppt., v.; March 31, Suppt., v.; April 28, Suppt., vii.; May 26, Suppt., v.; June 30, Suppt., v.; Communications, Personal and Impersonal Styles in, Dr. N. R. Campbell, 1021; Fact and Fancy, 785; Faculty, The Range of the, 269; Research, Pure, and Electrical Engineering Practice: The Interaction of, A Course of Advanced Lectures delivered before the University of London, October and November 1926, Dr. J. A. Fleming, 130; Terminology and its Annexation, J. L. Dunk, 137
Sclareol, the Principal Constituent of Essential Oil of Sage, Volmar and Jermstad, 694
Scots Pine, The Value and Quality of the, in the North of Great Britain, A. D. Richardson, 431
Scott, John, medal and premium, Dr. H. E. Ives presented with the, 394
Scottish Sea Trout, G. H. Nall, 184
Sea Fog Particles, Salt Crystals as Nuclei of, Sir Napier Shaw, 866
Season-cracking of Small-arms Cartridge Cases during Manufacture, F. S. Grimston, 442
Secondary: Electrons, The Emission of, and the Excitation of Soft X-rays, Prof. O. W. Richardson, 969; Radiation, A New Type of, Prof. C. V. Raman and K. S. Krishnan, 501
Seessel fellowship of Yale University, election of Dr. Ethel M. Poulton to the, 967
Segmental Interchange and Crossing-over, Dr. J. Belling, 282
Selene: or Sex and the Moon, Prof. H. M. Fox, 981
Selenia bilunaria Esp., A Further Induction of Melanism in, and its Inheritance, Prof. J. W. H. Harrison, 157
Selenium, Bubbles of, Production of, Major C. E. S. Phillips, 172
'Self-Adaptation' in Biology, Dr. E. E. Fournier d'Albe, 14; W. W. L., 172
Seltenen Erden, Die, vom Standpunkte des Atombaues, Prof. G. v. Hevesy, 168
Semi-diurnal Pressure Wave in the Earth's Atmosphere, Origin of the, E. V. Newnham, 353
Semites: Lectures on the Religion of the, the Fundamental Institutions, the late Prof. W. Robertson Smith. Third edition, with an Introduction and Additional Notes by Dr. S. A. Cook, 704
Sensori-motor Consequences of Passive Rotary and Rectilinear Oscillation of the Body, R. C. Travis and R. Dodge, 346
Separating Funnel, A New, 398
Sequoia Trees, Condition of the Giant, in the Yosemite National Park, 723
Serpentines of the Shetlands, Dr. F. C. Phillips, 185
Sewage Treatment, The Activated Sludge Process of, G. B. Kershaw, 165
Sex and the Gene, Dr. A. Walton, 934
Sexuality in Animals, The Genetics of, Dr. F. A. E. Crew, 934
Shark Fishing, Commercial, 653
Sheep Dips, 959
Shipworms in San Francisco Bay, 832
Shore Line Topography, T. Hay, 514
Shortt Free Pendulum Clocks, The Accuracy of, Dr. J. Jackson and W. Bowyer, 868
Shrew Mouse, The Identity of the Spirochæte of the, and the Human Spirochæte of Dakar, C. Mathis, 229
Sight: Light and, T. Smith, 242; Sir. J. Herbert Parsons, 243; Prof. H. Hartridge, 616
Silicates, Researches on the, E. Cherbuliez and P. Rosenberg, 122
Silk: Acetate, and its Dyes, C. E. Mullin, 739; Artificial, The Manufacture of, with Special Reference to the Viscose Process, E. Wheeler, 739; On the Production of, by Species of the Genus Hilara Meig. (Diptera), H. Eltringham, with an Appendix on the Habits of the Species, by A. H. Hamon, 344
Silkworm Parasite, A Mite on a, Dr. Chujiro Sasaki, 71
Silurian Corals, R. Wedekind, 727
Silver: Chlorate, Structure of, A. Ferrari and C. G. Fontana, 229; Halides, The Inner Photoelectric Effect with, Dr. S. E. Sheppard, 574; Nitrate Concentration Cells in Acetonitrile and Benzonitrile, F. K. V. Koch, 772; Solutions for use with Sea Water, Standardisation of, T. G. Thomson, 921; Standard, Effect of Quenching and Tempering on the Mechanical Properties of, A. L. Norbury, 484
Single-layer Problem in the Atmosphere, The, and the Height-integral of Pressure, Dr. L. F. Richardson and R. E. Munday, 405
Sirius Changed Colour? Has, Prof. T. J. J. See; E. Dittrich, 296
Size: Factor in Plant Morphology, The, with Special Reference to the Stele, Prof. F. O. Bower, 777; in Relation to Internal Morphology, (3), C. W. Wardlaw, 558
Skate Raja erinacea Mitchill: The, a Laboratory Manual, Prof. C. W. Creaser, 384
Skeletal Muscles, The Elasticity of, J. Lindhard, 78
Skjellerup's Comet, 147, 475
Slag, Coke Breeze, and Clinker as Aggregates, F. M. Lea and F. L. Brady, 436
Slaughter of Animals (Scotland) Bill, The, 959
Sligo: Artefacts, The: Dr. L. S. Palmer, J. W. Jackson, and W. O'B. Pierce, 501; J. Reid Moir, 908; A. L. Armstrong, M. C. Burkitt, H. Dewey, D. A. E Garrod, and R. A. Smith, 137; Implements, Geological Features of the Sites of the, Prof. O. T. Jones and Prof. P. G. H. Boswell, 861; The Palæolithic Implements of, J. P. T. Burchell, 983
Slow Combustion, Ionisation and Chemical Change during, Bennett and Mardles, 259
Smithsonian Institution of Washington: Dr. C. G. Abbot elected secretary of the, 181; Annual Report, 216; 510
Smut Fungi, The Physiology and Genetics of the, S. Dickinson, 157
Snail, Blood of the, The Molecular Concentration of the, M. Duval, 194
SO$_2$, The Determination of, The Effect of Other Reducing Substances on, J. W. Black and B. J. W. Warren, 265
Social: Ethics, or Present-day Conflicts, Sir Oliver Lodge, 893; Hygiene, The Task of, Havelock Ellis. New edition, 415; Life, The Foundations of, Prof. H. P. Fairchild, 415; Science, 415; Structure of England and Wales: A Survey of the, as illustrated by Statistics, Prof. A. M. Carr-Saunders and D. C. Jones, 389
Society: Islands Technology, W. C. Handy, 434; The Science of, Prof. W. G. Sumner and Prof. A. G. Keller, 3 Vols., 415

Sodium : Chloride, contained in Irrigation Water Action of the, on Certain Plants, N. Passerini and P. Galli, 607; in Plants, The General Presence of, G. Bertrand and Mme. M. Rosenblatt, 345 ; Ionised, Spectrum of, K. Majumdar, 423 ; O. Laporte, 941 ; Permanganate, Pharmacological Experiments with, injected Endovenously, L. Sabbatini, 694

Soil : Scientific Study of the, An Introduction to the, Prof. N. M. Comber, 167 ; 'Stratometer' : The, A Method for the Examination of Deep-lying Soil, Moh$^{ed.}$ Zaghloul, 537

Solar : Activity, Recent, 220, 806 ; and Terrestrial Magnetic Phenomena, The Correlation of, Prof. S. Chapman, 989 ; Atmosphere, The Construction of the, S. B. Nicholson and N. B. Perrakis, 523 ; Corona, Spectrum of the, The Origin of the, Prof. Meghnad Saha, 671 ; Radiation, The Filtration of the, by Ozone, G. Déjardin, 657 ; Telescope, An Inexpensive, and Spectrohelioscope, Prof. G. E. Hale, 676

Solid : Bodies and Gaseous Bodies, The Triboelectrical Effect between, E. Perucca, 733 ; Dipleidoscope Prisms, Prof. C. V. Boys, 1040

Solubility of Water in Liquid Carbon Dioxide, The, H. H. Lowry and W. R. Erickson, 116

Solutions, The Nature of, Prof. H. E. Armstrong, 48

Solvay, Institut International de Physique, Conductibilité électrique des métaux et problèmes connexes, 162

Sonic and Ultrasonic Waves, Transmission of, through Partitions, Prof. R. W. Boyle, 56

Sound Waves : High Frequency, of Small Intensity and their Biological Effects, Prof. E. N. Harvey and A. L. Loomis, 622 ; in Resonators, The Amplitude of, E. G. Richardson, 926

South : Africa : Indigenous Forest Trees of, Dr. J. Phillips, 221 ; Royal Society of, Prof. W. A. Jolly elected president, 880 ; Union of, List of serial publications available for consultation in the Libraries and Scientific Institutions of the, A. C. G. Lloyd, 39 ; African Institute for Medical Research, Report for 1926, 334 ; Australia : Discovery of Fossil Fauna of Ancient Annelids and Arthropods in, Sir Edgeworth David, 837; Iron Ore in, 222 ; The Crustaceans of, H. M. Hale. Part 1, 669 ; -Eastern Union of Scientific Societies, Annual Congress ; Sir Arthur Keith elected president of the Brighton meeting, 1037 ; Staffordshire Coalfield (south of the Bentley Faults), The Geology of the Southern Part of the, T. H. Whitehead and T. Eastwood. With contributions by Dr. T. Robertson, 132 ; Wales Coalfield, appointment of a committee on the, 995 ; -Western Naturalists' Union, Report of the, 960

Southern Cross, Flight of the, 958

Spanish : Fever, The Presence in Morocco of the Spirochæte of Recurrent, C. Nicolle and C. Anderson, 814 ; Fowl, White-faced, Altered Character in the, F. Finn, 246

Species, Origin of, Natural Reactions and the, Profs. A. R. Olson and G. N. Lewis, 673

Spectra : and Atoms, Prof. A. Fowler, 341 ; Excitation of : Indirect, R. Frerichs, 477 ; by High Frequency Oscillations, M. Ponte, 243 ; J. R. Clarke, 282

Spectral Lines ; after Reflection, The Absence of Enlargement of, Y. Rocard and P. de Rothschild, 406 ; Intensities of, Some Methods of estimating the, W. H. J. Childs, 484

Spectrograph with Concave Grating, The Automatic Regulation of a, A. Cotton, 345

Spectrophotometry, On Methods and Applications in, Cecilia H. Payne and F. S. Hogg, 659

Spectroscopy, Modern, 741

Spezia, Gulf of, The Anemological Regime of the, R. Bilancini, 779

Spherical Harmonics : An Elementary Treatise on Harmonic Functions, with Applications, Prof. T. M. MacRobert, 818

Spiders : Spermatogenesis in, Dr. E. Warren, 964 ; The Classification of, Prof. A. Petrunkevitch, 843

Spinax niger Cloquet, The Luminescence of the Dogfish, C. F. Hickling, 280

Spiral Nebulae, The Distances of the, R. Hess, 997

Spirochæta Duttoni, The Neurotropism of, C. Levaditi and T. E. Anderson, 606

Spitsbergen, Glaciers of Edge Island, H. G. Watkins, 435

Splanchnic Nerves, Functional Differences between Left and Right, J. H. Thompson, 540

'Sports' : and 'Reversion,' Prof. M. Drummond ; The Writer of the Notes, 575

Sports Photographs, Apparent Distortion in, Dr. T. J. I'a. Bromwich, 829

Sprays for Fruit Trees, Time of Application of, H. R. Briton-Jones and A. H. Lees, 258

Squalus acanthias Linné, and *Squalus sucklii* Gill, The Blood Vascular System of the Spiny Dogfish, C. H. O'Donoghue and Eileen (Bulman) Abbott, 558

Square Roots and the Decimal System, G. E. W. Dodwell ; A. R., 907

Staining and Structure in Microscopic Anatomy, Dr. J. A. Murray, 726

Standard of Mutual Inductance, The N. P. L. Primary, 151

Starch and Cambial Activity in the Woody Twig, 600

Starfishes, Fission in, E. W. Bennett, 476

Stark : Components of Hα, Observed Relative Intensities of, Dr. J. S. Foster and M. Laura Chalk, 830 ; Effect : and Series Limits, Dr. Jane M. Dewey and Dr. H. P. Robertson, 709 ; of the Fine-structure of Hydrogen, The, R. Schlapp, 1041

Star Streams, The Theory of Two, and the Ellipsoidal Theory, V. Nechvile, 733

Stars : Double, Micrometric Measurement of, Personal Equations in the, S. de Glasenapp, 657 ; Life in the, An Exposition of the View that on some Planets of some Stars exist Beings higher than ourselves, and on one a World-Leader, the Supreme Embodiment of the Eternal Spirit which animates the Whole, Sir Francis Younghusband, 200 ; in Planetary Nebulæ, Temperatures of, H. Zanstra, 790 ; New : A Suggested Cause of, M. O. Johnson, 842 ; The Physical Conditions in, S. R. Pike, 522 ; The, Dr. G. Forbes, 1015 ; Variable, The Ballistic Theory of, C. Cannata (2), 1043

Statesman's Year-Book, The, 1928. Edited by Dr. M. Epstein, 937

Statistical Mechanics with Applications to Physics and Chemistry, Prof. R. C. Tolman, 492

Statistique mathématique, Prof. G. Darmois, 825

Steam Wells : and other Thermal Activity at the Geysers, California, Drs. E. T. Allen and A. L. Day, 720 ; of California, The, Prof. A. Holmes, 729

Steel cored Aluminium Conductors, E. T. Painton, 480

Stellarastronomie, Prof. H. Kobold, 901

Stellar : Astronomy, An Outline of, P. Doig, 901 ; Parallaxes from Allegheny Observatory, 550 ; Photographs, Measurements of, Use of Diffraction Effects in, Prof. A. Pollard, 246 ; Radiation : and the Nature of the Universe, Sir Oliver Lodge, 711 ; W. W. L., 749 ; What becomes of, Prof. B. Brauner ; Dr. J. H. Jeans, 674 ; Thermodynamics, Prof. S. Rosseland, 700

Stencil Craft, F. J. Glass, 569

Stereoscope, The, Dr. R. S. Clay, 431

Stereoscopic : Kaleidoscope, A Portable, Dr. R. S. Clay and Sir Richard Paget, 483 ; Notes, Rev. H. C. Browne, 521 ; Parallaxes of 125 *B*-type Stars, D. L. Edwards, 598 ; Photographs of Crystal-Structure Models, Dr. A. E. H. Tutton, 75

Sterility in American Marriages, A. J. Lotka, 659

Sterols, Photochemical Activation of, A Quantitative Study of the, R. J. Fosbinder, F. Daniels, and H. Steenbock, 1000

Stichococcus, The Specificity of, more particularly from the Soil of the [Swiss] National Park, F. Chodat, 657

Stocks, Garden, Chromosome Mutations in, Dr. H. B. Frost and Mrs. Mann Lesley, 477

Stoke-on-Trent, The Freedom of, conferred on Sir Oliver Lodge, 471

Stomatal Frequency, Dr. E. J. Salisbury, 71

Stomiatoid Fishes, A. E. Parr, 843

Stone Celts from India, J. H. Hutton, 148

Storage Batteries, the Demand for, E. C. M'Kinnon, 144

Storm-Floods, The Forecasting of, 363

Storms, Great, C. Laughton and V. Heddon, 400

Strabometric Manograph, A, with Deformable Electric Condenser, J. Villey and E. Hochard, 41

Stratigraphic Chronometer of Saint-Nazaire-Penhoët, The, and the Age of Glozel, P. Combes, 194
Streatfeild Memorial Lecture, O. F. Bloch, 474
Street Lighting, W. J. Jones, 116
Streptococci, The, Dr. W. M. Scott, 701
Stress, The Distribution of, Round a Circular Hole in a Plate, W. G. Bickley, 970
Striated Muscle, The Structure of, from its Optical Properties, R. Lutembacher, 345
Stromboli, The Augite and Chrysolite of, A. Brun, 78
Submarines, Safety Apparatus in, Laubeuf, 486
Südtiroler Dolomiten: Das Grödener-, Fassa- und Enneberggebiet in den, Geologische Beschreibung mit besonderer Berücksichtigung der Überschiebungserscheinungen. Dr. Maria M. Ogilvie Gordon, 1 und 2 Teil: Stratigraphie-Tektonik. 3 Teil: Paläontologie, 83

Chemistry as a Career.

A GREAT deal is being said and written at the present time about the teaching of science and the prospects of careers for trained specialists in its numerous branches. The serious teaching of science is no longer confined to a few schools, for it is now widely accepted that even the properly educated layman should possess some knowledge of the general principles of physics, chemistry, and biology. An indication of the educational trend may be discerned, for example, in the recent provision of magnificent laboratories at Clifton College (NATURE, June 11, 1927, p. 871), and in the curricula of the remodelled City of London School, in which “general science, including biology, will be taught on the classical side, physics-with-chemistry on the modern side, while on the science side limited specialisation in physics, chemistry, and biology will be possible” (NATURE, Dec. 24, 1927, p. 936).

Although, apart from occasional conflicts between the claims of physical and biological science, it may be comparatively easy to cater in the secondary schools for the future layman in science, the potential specialist presents a difficult problem to headmasters and parents. At what age can a boy's aptitude for a particular branch of science be judged? How is he to be enabled to demonstrate that aptitude? How far should he be allowed to specialise at school in the field concerned? To what extent can a would-be specialist in science count upon a satisfactory career? These are some of the more insistent questions which press for an answer; and we may briefly consider them in this place, particularly in so far as they affect the profession of chemistry.

The provision of answers to the first two of them is a matter for the secondary schools; for, given a reasonably broad basis of secondary school education in science, there should be little difficulty in diagnosing aptitude before the boy is ready to enter the university.

Coming to the third query, and focussing attention upon chemistry, we cannot escape the impression that there is a current tendency in certain secondary schools to carry specialisation very far—perhaps too far—with apt pupils. This tendency, in turn, appears to be largely a response to the increasingly difficult examination papers which determine the award of entrance scholarships from the schools to some of the universities. The lot of the master who is preparing boys for chemistry in such examinations cannot be a particularly happy one; for, besides covering the old inorganic field, he has to bear in mind that the papers may deal mainly with physical chemistry; moreover, examiners do not hesitate upon occasion to include questions in organic chemistry which might well give pause to a second-year university student in that special branch of the subject.

It is not surprising, therefore, that many of the precocious specialists who have carried the study of chemistry so far in a limited time should possess little or no knowledge of biology, and that others should be regrettably deficient in English, mathematics, and other fundamental subjects. The discovery of a particular aptitude in a pupil is always welcome, and a judicious fostering of the favoured subject is essential; nevertheless, at school, and in the earlier years at the university, a pupil should be restrained from inordinate specialisation until he has secured the necessary basis of a well-proportioned general education. There is much to be said for the adoption of a broader test of intelligence and merit than the specialised examinations which are now so often imposed upon candidates for entrance scholarships to the universities.

Any query dealing with the prospects of a satisfactory career for pupils or undergraduates who are inclined to adopt chemistry as a profession is bound to raise complex issues. First of all, how is a satisfactory career to be estimated? Even if the simple quotation of a possible salary at a given age be accepted as sufficient, the question remains exceedingly difficult to answer. Perhaps the greatest stumbling-block in a discussion of this kind lies in the fact that chemistry provides a multitude of diverse professions rather than a single homogeneous profession. As a minor result of the War, few intelligent laymen are likely at the present day to confuse the so-called 'scientific chemist' with the pharmacist, or apothecary (why, by the way, cannot this honourable old name be resuscitated?); many, indeed, might even succeed in attaching such distinguishing adjectives as 'academic,' 'research,' 'analytical,' and 'industrial,' to the term 'chemist.' However, the very title of 'chemist' is so misleading in the British Empire that the Registration Committee of the British Association of Chemists has recently replaced it by the term 'chemical practitioner.'

A preliminary indication of the scope of the profession is afforded by the fact that candidates for the fellowship of the Institute of Chemistry may qualify in any one of the following eight branches: inorganic, physical, organic, agricultural, or general chemistry; the chemistry (including microscopy) of foods and drugs, and of water; biochemistry; and chemical engineering. This, however, is only the beginning of the classification. A glance at the *Journal of the Society of Chemical Industry* is sufficient to reveal that an industrial chemist may specialise in any one of twenty-three arbitrarily selected sections, and many of these sections may be subdivided almost indefinitely. Some of the great chemical industries centre, indeed, around a single material, or a group of allied materials, such as sulphuric acid, alkalis, ceramics, metals, glass, petroleum, alcohol, cellulose, cane-sugar, fats, paints, leather, india-rubber, medicinal chemicals, dyes, explosives, etc. Add to these considerations the fact that the industrial chemist—irrespective of the particular manufacture in which he is interested—may be occupied with any combination of duties comprehended under such labels as 'research,' 'analysis,' 'control,' 'administration,' and many others, and one begins to realise the innumerable ramifications of the chemical profession.

It is thus apparent at the outset that this profession possesses as many diversities as the British Empire, and that it provides scope for all sorts and conditions of chemists. Just as a Fijian would not feel at home in Labrador, so would a chemist who has specialised in the alkali industry experience a certain sense of strangeness if required to conduct research work on the constitution of a new alkaloid. Moreover, it is quite as difficult to legislate effectively for the complex corporation of chemists as for the complex racial association of the British Empire. That is why chemists, in spite of the beneficent activities of the Institute of Chemistry, are unable to safeguard the interests of their profession in a generally acceptable manner. The Institute publishes, however, a comprehensive list of official appointments which are, or may be, held by chemists, under the title of "Official Chemical Appointments"; and it is specially concerned with the creation of such posts as well as with the education and registration of professional chemists competent to fill them. Its 5300 fellows and associates represent many aspects of chemical science and practice, and they form just as unified a professional organisation as is found in similar institutions of civil and mechanical engineers or of medicine.

Specialisation is, however, the penalty that has to be paid for progress. If, therefore, a young man resolves whole-heartedly—in colloquial phrase—to 'take up chemistry,' his decisions are by no means at an end. Under modern conditions he has to specialise again—this time within the subject, and possibly in one or more of the branches recognised by the Institute of Chemistry. Eventually, he may favour academic, analytical, or industrial work. In the first contingency—in the absence of striking powers—his promotion is likely to be slow, and he may be heading for the forties before he achieves even a modest competency. If he succeeds in securing a good footing in analytical practice, or, better still, in industrial chemistry, his progress is likely to be far more rapid, particularly if he possesses adaptability and personality. In making his crucial decisions he will look for guidance to his university teachers, who should maintain the closest possible touch with the leaders in industrial chemistry.

At the present time, while opinion is practically unanimous upon the very great difficulty of finding openings in chemical industry for men of second-class attainments, and for women chemists of even the highest qualifications, there are two distinct currents of feeling regarding the prospects for trained men of undoubted first-class ability.

On one hand, there is talk of a 'glut of chemists,' as an aftermath of the War; and there is little doubt that some chemists in Great Britain have been forced to abandon their profession since 1918, owing to the difficulty of securing satisfactory appointments. Communications from disillusioned or disgruntled chemists appear at frequent intervals in the technical press. One reads of a letter offering a wage of 1*s*. 2*d*. per hour to a graduate with three years' industrial experience, in a district where an unskilled labourer receives 1*s*. 7*d*. per hour. A correspondent complains (NATURE, Mar. 19, 1927, p. 432) that a lecturer in organic chemistry is paid at the rate of a dock labourer; another refers to an advertisement in which "a chemist, bacteriologist, 'medicolegalist,' organiser, lecturer, etc., is offered the princely salary of £400 per annum."

On the other hand, it has recently been stated in an authoritative chemical publication that "chemists are not worse paid than other professional men, and . . . that in the majority of cases they are paid as much as they are worth. Those who call attention to the low salaries offered to junior chemists will find the same feature in other professions. . . . It took us several years to realise how much more valuable and how much better remunerated is the knowledge of affairs and of men than the knowledge of a science, or of law, or of History or literature. . . . The supply of the clerk, the book-man, the man educated in schools and universities exceeds the demand." That the last statement does not apply at present to the trained chemical specialist of first-class ability is evident from the categoric pronouncements of prominent leaders in the British chemical industry, to the effect that the supply of properly qualified chemists is inadequate. Here one may interpolate that the qualifications should include a sound general education, a first-class honours degree, or its equivalent, in chemistry, together with a couple of years' training in research.

Thus, Sir Alfred Mond is reported in the *Times* of Dec. 13 to have stated that

> "there was a definite shortage of scientific men in this country, and that was hindering research work. In his own company the number of men of the kind they wanted was far below the number they could absorb, and they had decided to approach headmasters with a view to selecting bright boys when still at school. Those boys would be assured that, if they would go through a university and obtain first-class degrees, they would not have to look for a job, but would be found one in his organisation, with remunerative salaries, at the moment they were ready to come. The company hoped in that way to do something from the beginning to make science a career, just as the Bar or medicine was now. They wanted a much greater co-ordination between the leaders in science in the universities and those who wanted the taught material. They wanted a conference at an early date so that those who were teaching could be told the directions in which their pupils would find work of advantage both to themselves and to those by whom they were employed."

Periodical conferences of this kind would undoubtedly be of value in correlating supply and demand and in providing opportunities for discussing other problems. For example, the cost of a training which includes five or six years at a university is naturally a serious consideration to many parents, and Sir F. D. Lugard in a letter to the *Times* of Dec. 17 makes the interesting suggestion that "there are probably many boys at our public schools who have shown a marked aptitude for science, and have borne a character for steady application to study, and would gladly agree to repay their university expenses by deductions from their subsequent salaries, if those expenses were provided in the first place by a firm which offered prospects of scientific research." It may be mentioned that a scheme of this general character was adopted some years ago with marked success by a certain enlightened and efficient chemical corporation in Australia.

Such opinions as those quoted above form a refreshing contrast to the narrow views of many of the uninformed laymen who have hitherto so often found themselves in nominal control of chemical enterprises. A good deal of the dissatisfaction to which reference has been made has probably been engendered by the unenlightened and conservative tendencies of the business man of the old school, who has been apt to regard the chemist in his factory in much the same light as the maid-of-all-work in his home. Under the new regime, the young chemist who enters a scientifically organised chemical corporation, with trained chemists in the highest administrative positions and on the board of control, will not suffer from the disadvantages which have so discouraged his predecessors. Provided that he is efficient, he will enjoy security of tenure, with, let us hope, an adequate pension provision; he will obtain the diverse experience which only a large organisation can offer; and the elastic system under which he finds himself will permit of his particular abilities being utilised to the best advantage.

To sum up this aspect of the discussion, it appears that at present, owing largely to the stimulating effect exerted upon the British chemical industry through the formation of Imperial Chemical Industries, Ltd., the prospects in this industry are decidedly promising for the new generation of properly qualified chemists. The directors of this great organisation are taking broad and patriotic views, and it is devoutly to be hoped, in the interests of Great Britain and the Empire at large, that their efforts to establish the British chemical industry upon an unassailable footing will be crowned with success. It should be the aim of the secondary schools and universities to aid in diverting into this vitally important group of key industries an adequate proportion of the best brains of the nation. That the realisation of this ideal will bring a fitting reward to the man of proved first-class ability is certain, especially if he combines with his expert knowledge of chemistry a *flair* for research, economics, administration, or business management.

Eastern Adepts and Western Science.

The Mysterious Kundalini (the Physical Basis of the "Kundali (Hatha) Yoga" according to our Present Knowledge of Western Anatomy and Physiology). By Vasant G. Rele. With a Foreword by Sir John Woodroffe (Arthur Avalon). Pp. xi + 112 + viii + 4 plates. (Bombay: D. B. Taraporevala, Sons and Co., 1927.) 3.8 rupees.

THE chief interest of this book, for most readers of NATURE, will consist in the description of the modification at will of certain physiological processes by a Yogi of Bombay. The Yogi demonstrated his powers before the Bombay Medical Union, and also before the students of a medical college (name of the college not given) and a few guests. On the latter occasion the author, who possesses the diplomas of F.C.P.S. and L.M. and S., and who is described by Sir John Woodroffe in his foreword as "a competent man of science," was selected, along with another doctor (unnamed), "to judge the truth of his statements," and was "told to report to the students what we actually saw and felt."

The Yogi, when told to stop his right pulse, took a deep breath and made a forcible expiration; whereupon for the first two or three seconds the pulse was very much accelerated; then came a slowing, and then a stoppage, which lasted for more than two minutes with the interposition of two or three beats at the end of the second minute. During this time his hand and fingers were "a bit shaky," and there was some twitching in his fingers; the pulse on the other side was normal, and the muscles of the arms and forearms were quite soft and pliable. The pulse on the left side, and the temporal pulse, could also be stopped at will. "When the radial pulse of one hand was stopped, the circulation in the whole arm was stopped, but when the pulsation in the temporal artery was made to stop, the carotid artery was still beating, showing thereby that the checks used by him were above the brachial artery in one case and above the carotid in another."

The heart beats, as heard by the stethoscope, could also be stopped. After the same process of deep breathing and forced expiration the heart slowed and stopped; "the duration of complete stoppage of the beat of the heart was for six seconds by the watch." When the Yogi was examined by X-rays, before the two observers and eight other medical men of repute, and told to stop the beating, his heart contracted so that its apex was about two-thirds of an inch internal to its normal position; the apex beat was inaudible, but the rhythmic contraction of the heart was still present; the beats, recorded on a cardiograph (reproduced), were much smaller in amplitude (about two-thirds of the normal, as shown on the tracing) and less frequent (60 per minute).

This Yogi also showed "some rare feats of archery, such as splitting of hair and thread by an arrow darted at them from a distance of about 15 to 20 feet. He broke an iron chain three-eighths of an inch in thickness by a mere pull of his body; one jerk, and crack went the chain in two pieces." Physically he is described as being slender in body, legs long and thin, and calf muscles showing insufficient physical exercise.

The Yogis are adepts of the science of yoga, by which the embodied spirit, jivátma, which is a part of the universal spirit, paramátma, is made to become one with the universal spirit by certain physical and mental exercises; yoga is the "union or linking together of man with God." The necessary physical and mental exercises are arranged in eight steps; the physical exercises are concerned with posture and regulation of the respiration. The author states that all the physical practices of yoga are directed towards bringing the sympathetic under [conscious] control, and that this control is effected through the plexuses of the autonomic nervous system. Leaving aside the Yogi's feats of skill and strength, the author's explanation of the modifications of the circulation is that these are due to an acquired conscious control of the sympathetic nervous system. But "the ultimate aim of the Yogi, in the various practices, is not to acquire and manifest the various supernatural powers, which only come to him on his onward march of getting himself absorbed with the Infinite."

According to the Tantric manuals, the stimulation of the 'chakras,' which the author identifies with the sympathetic plexuses, is always through 'Kundalini'; by establishing the control of the will over Kundalini we can subjugate the whole of the autonomic nervous system. But, though numerous interpretations have been given, Kundalini has always been a mystery; the author identifies her (the feminine is apparently correct) with the vagus nerve, which has connexions with the several plexuses of the sympathetic in the thorax and abdomen, and more particularly with the right vagus. The control is obtained by practising certain 'catches' (Bandhá) and attitudes (Mudrá) during the process of Pránáyáma, the fourth of the eight steps in the training of the Yogi. The author gives a full account of the various steps, and especially of the physical exercises, by which yoga is attained, and illustrates this by a number of photographs. But though the various practices of yoga appear simple and easy of achievement on paper, they are all to be learnt at the feet of the master; "it is of paramount importance that the instructions should be received by a student from an adept."

A few words of criticism may be added. The author does not discuss the Yogi's feats of skill and strength, yet some notice must be taken of these also. If the description of the splitting of a hair, or even of a thread, by an arrow from a distance of 15 to 20 feet is to be taken literally (and if not, the value of the whole account is much depreciated), it would seem probable that either trickery on the part of the performer, or an abnormal mental condition of the spectators, must come into the reckoning. Again, we are not told who supplied the iron chain that was broken by "one jerk" of this physically poorly developed adept.

The author would presumably explain the stoppage of the radial pulse, produced at some point above the brachial (that is, by occlusion of the subclavian or axillary artery), by a localised contraction of the musculature of the vessel wall occasioned by a voluntary impulse passing along the sympathetic fibres. But it seems improbable that even the most powerful stimulation of the sympathetic—even an experimental stimulation—could cause complete occlusion of the larger arteries; it is to be remarked, too, that a graphic record of the pulse was not taken; possibly, if this had been done, pulsation might have been found to be still present, as in the case of the heart. To forestall criticism, moreover, we ought at least to have been assured that there was no possibility of anything being concealed in the axilla against which the axillary artery could be compressed, and that the subject did not possess cervical ribs which in some posture, for example, when the shoulder was depressed, could exercise compression on the subclavian. A diminution in the temporal pulse might conceivably be brought about by the compression of the external carotid from inside, by some hard body in the throat; at least, such possibilities should be definitely excluded. The effect of forced respiratory movements on the heart is well known; we seem to remember that the earlier editions of Huxley's "Lessons" stated that the heart-beats could be stopped temporarily by strong sudden inspiratory or expiratory efforts with nostrils and mouth closed—with an added note, however, that the experiment was not free from danger.

The author's claims on behalf of the Yogi can thus not be accepted until there is evidence of the application of a more rigid criticism. The book has, however, a distinct value as describing and illustrating for western readers the physical training of the Yogi, and as an attempt at interpreting in modern terms the difficult pseudo-anatomical descriptions of the Tantric texts.

J. STEPHENSON.

British Deer.

Hunting and Stalking the Deer: the Pursuit of Red, Fallow, and Roe Deer in England and Scotland. By Lionel Edwards and Harold Frank Wallace. Pp. xi + 274 + 48 plates. (London: Longmans, Green and Co., Ltd., 1927.) 63*s*. net.

WHILE the sumptuous volume on deer-stalking and stag-hunting whereof Mr. Lionel Edwards and Mr. Frank Wallace are joint authors forms a notable addition to the literature of field sports, for the field naturalist it has a strain of melancholy, inasmuch as it records marked degeneration in the noblest of our native land fauna—*Cervus elaphus*. "It is curious," observed Mr. Walter Winans in his recent work, "Deer-breeding for Fine Heads" (London, 1913), "that Scottish stags are at the present time the worst in Europe." It would be curious, indeed, if they were not so, having regard to the conditions of climate and food supply which they have to encounter in winter. By nature and original habit the red deer is a woodland animal, only resorting to the hilltops in summer heat to escape the torment of flies and to browse on the flush of upland grass, but ever returning to the woods for shelter and food in winter. Now that man has felled the forest and claimed all the low ground for his industry and crowded habitation, the red deer are confined throughout the year to storm-swept wastes at high altitudes. The term 'deer forest' remains only to connote some of the bleakest and most treeless tracts in North Britain. The real wonder is that British red deer have not deteriorated still further from the magnificent creatures that roamed the Caledonian forest of yore, whereof the bones and antlers exhumed from peat-mosses and tidal estuaries prove to have been no whit inferior to animals of the same species now inhabiting the Carpathians, the Caucasus, and certain well-wooded English parks.

Two such antlers lie before the present writer. They are not a pair; one with seven points has part of the skull attached and measures 37 inches along the outer curve and 7¼ inches in circumference between brow and bay. The other is a cast horn, 38 inches long, with only six points remaining, the brow tine having been broken off; the bay tine is of the extraordinary length of 20¼ inches. These antlers are among very many others recovered from the alluvium in the estuary of the Cree in the work of drawing out of the clay huge oak trunks, wreckage of the Pleistocene ice.

As indicated by the title of their book, the authors treat of deer almost exclusively from the sportsman's point of view; but Chaps. xxvi. and xxvii. contain some interesting notes upon the habits of red deer, of which not the least remarkable is the readiness with which they take to the water and the distance to which they will swim, even when not pursued. They cross freely from isle to isle of the Hebrides, and an instance is recorded of a stag being captured in Kilbrannan Sound four miles at sea, "apparently swimming for Arran, which is twelve miles distant from the mainland" (p. 132).

In view of the great number of deer killed every year in Great Britain, it is strange in how little general esteem venison is held as food. Gourmets appreciate it; but in most houses it is taboo in the servants' hall. Sportsmen have come to prize a good 'head' more highly as a trophy than a fat haunch as a delicacy. Indeed, a great part of the volume under notice is occupied with a discussion of the antlers of the red stag, with long lists of detail in their dimensions and variety.

> "The chief reason," writes Mr. Wallace, "why the horns of the *Cervidæ* present so many features of interest lies in their never-ending variety. Place twenty of the finest heads of any other species of game alongside one another, and whether they be kudu, sable, ibex, or the great sheep, you will notice very little difference. . . . No two heads of red or roe deer . . . are alike even to a casual eye, and so to the study of their horns attaches a peculiar interest" (p. 95).

The authors make no reference to what is, after all, the most remarkable feature in the antlers of deer, namely, that alone among Ungulates the Cervidæ grow solid horns and cast them annually. The giraffe and rhinoceros also carry solid horns, but a single pair of these, like the hollow horns of oxen, goats, and antelopes, serve them throughout life for offence, defence, and ornament; whereas the far heavier armature of a red stag has to be fashioned afresh, with considerable pain and irritation, each summer, only to be cast off in the following spring. The consequent waste of material in a herd of deer is considerable, especially among reindeer, whereof both sexes carry palmate antlers. Among the remains referred to above as recovered from the estuary of the Cree is a pair of red stag's antlers weighing exactly 18 lb.

Purpose in the waste of such fine armature baffles conjecture, but there is no doubt about the purpose for which it was grown.

> "Deer, as is well known, are great fighters, and when with the hinds a stag leads a pretty strenuous life. . . . I doubt if a big beast with a large number of hinds gets any sleep at all for days, one might almost say weeks, on end. Watchful rivals are for ever hanging on the flanks of his harem ready to dash in and cut out a stray hind or two if their master's alertness is relaxed for a moment. Towards the end of October, worn to skin and bone, with bloodshot eyes, completely exhausted, he can no longer display his former activity, and smaller beasts may evade his weakened fury."

The volume is well and profusely illustrated, the coloured plates by Mr. Lionel Edwards being very beautiful. HERBERT MAXWELL.

Quanta.

Handbuch der Physik. Herausgegeben von H. Geiger und K. Scheel. Band 23: Quanten. Redigiert von H. Geiger. Pp. ix + 782. (Berlin: Julius Springer, 1926.) 57 gold marks.

IT is little more than a generation ago since Planck first formulated his quantum theory to explain the observed distribution of intensity of black-body radiation in its dependence on frequency and temperature, and so introduced the discontinuity idea into the description of natural processes. Meanwhile, the new theory has thrown out its feelers into practically every branch of physics, and developed with such amazing rapidity that it appears both fitting and natural that a special volume of the "Handbuch der Physik" should be devoted to it. Even so, not all the applications of the quantum theory are embodied in the present volume. Subjects such as the statistical applications of the theory, its relation to chemistry and to molecular structure, and certain aspects of the theory of band spectra have been relegated to their appropriate volumes. Furthermore, the epoch-making developments of quantum mechanics by Heisenberg, Born, Jordan, Dirac, L. de Broglie, Schrödinger, and others, are not included, but will doubtless receive their due share of attention in later volumes of the 'Handbuch.'

The editor has been particularly fortunate in his choice of contributors, all of whom are in the forefront of the branches on which they write. In its production, too, the book is of exemplary clearness; the paper is good, the diagrams clear, and the photographic reproductions bring out even the finer detail. Copious references to the literature occur at the foot of almost every page, an index is included, and nothing of importance appears to have been overlooked.

Chap. i. is more than the word chapter conveys. In a space of somewhat less than three hundred pages, W. Pauli, Jr., gives a complete statement of the quantum theory, which is masterful in its brevity. The underlying ideas are presented with remarkable clearness, and the experimental developments of the subject are everywhere kept in view. We can perhaps pay no higher tribute to the chapter than to state that it reaches the same high order of excellence as the author's well-known article on relativity in the "Encyclopædia of the Mathematical Sciences," which, at the instigation of Prof. Sommerfeld, was reprinted in separate book form. In three sections Dr. Pauli deals successively with the general principles of the quantum theory, the theory of the spectrum of atoms with a single electron, and with the spectra of atoms with more than one electron. Even in its more difficult parts the theoretical treatment is remarkably lucid, and we venture to express the hope that this article by Dr. Pauli may also be printed separately in book form and made available in English. A slight misprint occurs on p. 173 (footnote) in the spelling of Guthrie! Spectral notation is badly in need of standardisation, and is a constant source of confusion even to specialists. In this chapter Dr. Pauli has done his best to preserve clearness in this respect, for he devotes p. 278 to a statement of the term and quantum number notations as used by Sommerfeld, Landé, and by himself. His own notation has been arrived at after consultation with Sommerfeld and Hund, and it is to be hoped that co-operation will soon be exercised and uniformity attained through the medium of an international convention.

One of the most remarkable and striking features of atomic physics is the accuracy with which the various fundamental constants are known. The second chapter, comprising a theoretical and an experimental section, is concerned with the evaluation of Planck's constant h, and gives a critical and very valuable summary of the results. R. Ladenburg concludes that the best value of h in the present state of knowledge is $(6{\cdot}55 \pm 0{\cdot}01) \times 10^{-27}$ erg sec.

The absorption and scattering of X-rays is dealt with by W. Bothe in Chap. iii., and it need scarcely be said that the subject is ably and authoritatively presented, for the author himself has contributed in no mean measure to the work done in this field. Both theory and experiment are treated, and many useful numerical data are included. The older work is proportionately discussed, and more recent work (directional distribution of photoelectrons, Compton effect, etc.) is described in a clear and well-balanced manner. A brief appendix on the energy measurement of the rays is not only of theoretical interest, but also of importance in radiological practice.

H. Kulenkampff gives in Chap. iv. a full account of the continuous X-ray spectrum, the laws of its excitation, the energy distribution in the spectrum, as well as polarisation effects and the azimuthal distribution of intensity. The chapter contains much useful information, both experimental and theoretical, and is a valuable critical survey of the subject.

The fifth chapter owes its origin indirectly to the War, when the author, P. Pringsheim, spent the period of his unfortunate internment in Australia in the collection of material for his well-known book on "Fluorescence and Phosphorescence," in which he gratefully acknowledges the help afforded him by Profs. Lyle, Pollock, and Wellisch in procuring the necessary literature. The chapter is entitled "The Excitation of Emission by Radiation," and deals fully with resonance radiation, the disturbance of resonance radiation by collisions, the fluorescence and phosphorescence of organic compounds, the fluorescence of inorganic molecules, and crystal phosphors. This new and up-to-date treatment of a rapidly developing subject is most welcome, and Prof. Pringsheim has performed his task admirably.

Photochemistry is one of those border-line sciences which cannot be regarded as the prerogative of physicists. Too detailed an account of it is thus scarcely called for even in a handbook of physics. On the whole, we feel that W. Noddack has been judicious in the selection of his material, and the essential facts are presented clearly and well arranged in the forty pages of Chap. vi. In one or two instances, however, he has erred on the side of brevity, especially in the section on the effects of corpuscular rays. The latest reference to the action of α-particles in promoting chemical reaction is of pre-War date, whereas much valuable work has been done during the last few years, notably by S. C. Lind.

Our knowledge of atomic structure has made vast strides since the classical experiments of Franck and Hertz, and much of the progress made has resulted from the application of their method of retarding potentials in work on the "Excitation of Quantum Jumps by Impact." This is the title of Chap. vii., excellently written by J. Franck and P. Jordan, and it is one of the most valuable in the book, both in its clear statement of theory and in its presentation of experimental method. The authors deal with slow electrons, critical potentials and energy levels, the probability of excitation and ionisation, and kindred topics. The treatment is not only critical, but also delightfully lucid and complete. It is based on the authors' well-known book on the same subject.

Our Bookshelf.

Mikroskopische Physiographie der Mineralien und Gesteine: ein Hilfsbuch bei mikroskopischen Gesteinsstudien. Begründet von H. Rosenbusch. Band 1: *Die petrographisch wichtigen Mineralien und die Methoden ihrer Untersuchung.* Fünfte, neu bearbeitete Auflage von E. A. Wülfing und O. Mügge. Zweite Hälfte: Spezieller Teil. Fünfte, erweiterte Auflage von Prof. Dr. O. Mügge. Pp. xv + 555 - 814 + Tafeln 21 - 35 + 17 Tabellen. (Stuttgart: E. Schweizerbart'sche Verlagsbuchhandlung, 1927.) 33 gold marks.

THIS is the concluding instalment of the second half of the first volume of the classical work of Rosenbusch, which is a necessary part of the equipment of every student of petrology. It forms part of the fifth edition, the first after the death of the master. The fact that Prof. Mügge is responsible for it is a sufficient guarantee that the standard of the work has been maintained and that it has been brought thoroughly up-to-date.

The 'special' half of the volume deals with the physical, above all the optical, characters of the different rock-forming minerals by which they can be recognised. As much space as ever is devoted to the determination of the position of soda lime felspars in the continuous series from albite to anorthite. The use of the theodolite stage for the purpose had been already very clearly explained in the first or 'general' part.

An elaborate table for reference in identifying the different minerals presents some novel features. There is a separate category for minerals soluble in water. The biaxial minerals are not classed according to their crystallographic systems but according to their chemical nature. Whether this arrangement will help to facilitate the recognition of minerals remains to be tested by experience. The crystallographic system is indicated by Roman numerals, and it is rather disturbing at first to find that IV. means an orthorhombic mineral and not a tetragonal one, and VI. triclinic, not hexagonal.

The beautiful reproductions of mineral photographs remain one of the most attractive features of the book, and their number has been considerably increased.

J. W. E.

(1) *Laboratory Manual in General Microbiology.* Prepared by the Laboratory of Bacteriology and Hygiene, Michigan State College. Third edition. Pp. xxvi + 472. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1926.) 17*s.* 6*d.* net.

(2) *Les Microbes.* Par Prof. P. G. Charpentier. Avec un atlas de photomicrographies de P. Jeantet. (Bibliothèque générale illustrée, tome 5.) Pp. 77 + 59 planches. (Paris: F. Rieder et Cie, 1927.) 16·50 francs.

(3) *Dictionary of Bacteriological Equivalents: French-English, German-English, Italian-English, Spanish-English.* By William Partridge. Pp. xi + 140. (London: Baillière, Tindall and Cox, 1927.) 10*s.* 6*d.* net.

(1) DESIGNED as a guide to students and teachers of general microbiology, this volume deals with general morphological and cultural methods, the physiology of micro-organisms and applied microbiology. The last named is subdivided to include air, water and sewage, soil, dairy and plant sections. Animal diseases and immunity, and an appendix dealing with special media, stains, etc., are added. Each part is arranged in a series of exercises with instructions, questions, and a list of references.

It is possible that this volume might prove of value in outlining a course for students in general microbiology, since much useful material is included. The new classification of the Society of American Bacteriologists is not used in the book.

(2) Prof. Charpentier, in his small volume, aims at conveying to the lay mind some knowledge of microbes both useful and harmful to man. Well-known examples are used and described in an easily readable and interesting manner. A large number of photomicrographs are given at the end.

(3) As the author states, this little book of 140 pages is intended to serve as a supplement to the general dictionary. All the foreign words included have, for the most part, been taken from the bacteriological literature of the country concerned. In all, about 7800 words are dealt with, of which 2400 are French, 2600 German, 1200 Italian, and 1600 Spanish. Many of the words are not found in ordinary dictionaries.

The Elements of Telephone Transmission. By H. H. Harrison. Pp. vii + 147. (London: Longmans, Green and Co., Ltd., 1927.) 5*s.* net.

SINCE Heaviside developed the theory of the transmission of electric and magnetic waves in long distance telephone circuits, vast improvements have taken place in the technique of the construction of telephone lines. As Heaviside assumed that his readers were thoroughly familiar with mathematical theory, he omitted many essential steps in his proofs, and this makes it no easy matter to follow his reasoning. The ordinary telephone engineer who uses Heaviside's somewhat complicated formulæ would probably be unable to prove them. In general, also, the engineer has little grasp of the physical processes which operate on a long telephone circuit. Most of the books on the subject are of a very advanced character. We therefore welcome an addition to the scanty literature which is suitable for the elementary student.

The reader will find this book a good introduction to the standard text-books on the subject. It is divided into four chapters, the first being a purely mathematical introduction dealing mainly with the elementary calculus. Engineers seem to think that there is some special virtue inherent in writing j for $\sqrt{-1}$ and calling it an operator. We prefer to use the Greek letter iota, ι, for $\sqrt{-1}$ and D for an operator. We know that this has been the custom at Cambridge for many years.

The United States of America: Studies in Physical, Regional, Industrial, and Human Geography. By Prof. A. P. Brigham. Pp. x + 308. (London: University of London Press, Ltd., 1927.) 8*s.* 6*d.* net.

PROF. A. P. BRIGHAM is already well known as an authority on various geographical aspects of the United States, and those who were stimulated by his lectures in London and Oxford in 1924 will be glad to know that they in turn have stimulated the lecturer to prepare this well-proportioned and illuminating book.

Besides the students of the later secondary and the earlier university years for whom the work is specifically intended as a text, there must be a wide circle of readers who have wished for a trustworthy account—not too long, and not too technical—of the United States and its varied inhabitants as they are to-day. They need look no further: for here they will find a panoramic survey of all the leading facts; a summary which is masterly in its balance, and in its freedom from the cramped terseness of many small works on large subjects; and an outlook which is sane and unprejudiced. The author has attempted to write for both sides of the Atlantic. In Great Britain his book will be welcomed as making a notable contribution to the literature of a subject which deserves to be far better understood than it is. The book is beautifully illustrated, and is produced at a price that does credit to the enterprise of the publishers.

A Course of Volumetric Work for Day and Evening Students of Pure and Applied Chemistry. By E. Clark. Pp. vi + 146. (London: Sir Isaac Pitman and Sons, Ltd., 1927.) 4*s.* 6*d.* net.

THE subjects dealt with are standard solutions, acidimetry and alkalimetry, silver nitrate, permanganate, iodine, and dichromate, and a few unclassified estimations. The principles of the methods are well explained and careful directions are given for performing the experiments and calculations. The book is suitable for use in evening classes and also for university students of intermediate standard. In both cases the work of the teacher will be simplified by the careful explanations given. All the points which offer difficulties have been dealt with and the book may be recommended as distinctly better than most existing works of its size and scope.

Letters to the Editor.

Flame and Combustion.

PROF. H. S. TAYLOR, in a letter to NATURE of May 21, directed attention to work going on in his laboratory and continued in Sweden by Dr. Bäckström (*Medd. K. Nobel Inst.*, 6, 15, and 16, 1927). Dr. Bäckström has found that the photochemical oxidation of benzaldehyde in the liquid state is a chain reaction, and since the effect of inhibitors is the same for the photochemical as for the thermal reaction, the latter is almost certainly a chain reaction (*J.A.C.S.*, **49**, 1460; 1927). In our work on the combustion of hydrocarbons below their igniting temperatures, the effect of inhibitors (such as phenol or aniline) on the gaseous oxidation appears to be similar to their effect on the oxidation of benzaldehyde in the liquid state. Therefore, probably, the mechanism of oxidation is the same.

We are led, therefore, to the following general view of gaseous combustion. Reaction will commence when a sufficiently energetic molecule of fuel combines momentarily with an energetic oxygen molecule. A temporary peroxide in a high energy state is thereby formed. Among the several possible changes which may result, starting with a hydrocarbon, a breakdown into an aldehyde and a water molecule is quite a likely one. These molecules would possess not only the initial energy of activation but also the reaction energy, and on their next encounter with other fuel molecules (or oxygen molecules) could communicate sufficient energy to enable combination to occur and so start a reaction chain. Such a mechanism would explain why the initial stages of combustion are so much influenced by concentration. For example, a small quantity of acetaldehyde added to pentane makes little difference to the igniting temperature of the pentane, although the aldehyde alone ignites at a lower temperature. The reaction chains facilitating the oxidation of the aldehyde alone, cannot be started to the same extent in the mixture, as the collisions with the hydrocarbon molecules communicate insufficient energy to activate the latter.

The main significance of a reaction chain mechanism as regards ignition, is that a comparatively rare occurrence becomes a frequent occurrence locally; centres of high energy are thus established which, if diffusion is prevented, become centres of ignition. It is clear that some of the molecules may become deactivated by loss of energy as radiation; (chemiluminescence with pentane is visible 200° below the igniting temperature). Photochemical oxidation, however, is probably insignificant compared with the thermal reaction, and we have found illumination makes no appreciable difference to the igniting temperature, though it has been observed to affect the rate of reaction at considerably lower temperatures (Bennett, *Trans. Farad. Soc.*, **23**, 295; 1927). The upper limit for excitation of molecules would be given by the ionisation of the molecule, though often dissociation occurs before ionisation. Where dissociation does not take place and as the reaction proceeds more and more rapidly and the temperature rises, the chances of reaching higher energy states become greater and there is every probability that some ionisation occurs. In my view this is one of the later stages of combustion and not the essential primary step; the combination of a fuel molecule with an oxygen molecule is the essential initial process. Combustion naturally will be most intense in the regions of high ionisation, because there the most highly active particles are to be found. In the flame itself ionisation, for the same reasons, is intense.

Prof. Taylor mentioned the effect of the organic radicals with which the metal in an antiknock compound is associated. Our experiments showed that this effect was secondary (*Jour. Petrm. Techn.*, **13**, 244; 1927). These radicals would certainly influence to some extent the oxidation processes which are going on in the locality of the 'antiknock' molecule. Thus, ether added to petrol tends to prevent the inhibitory effect of lead tetraethyl by forming with it a fairly stable oxidation product, but I found no such effect to occur with nickel carbonyl and ether-petrol mixtures; nickel probably does not form a similar compound. The effect of an 'antiknock' is mainly that of an inhibitor of oxidation and it does not assist combustion as some have suggested, though its result may be to obtain the kind of combustion required.

The 'autocatalysis' in the initial stages of combustion to which I have referred is a 'joy to the antiknock soul,' because it provides a mechanism which can be readily slowed down by the breaking of the reaction chains. This, together with the point established in the papers cited that the antiknock acts in a high state of oxidation which can be taken to a lower state and then regenerated, seems to account satisfactorily for many of the facts.

I am afraid that the above remarks are not in terms to be appreciated by Prof. Armstrong. I should like to achieve his approval by interspersing a few 'hydrones,' but so few people appreciate their charms that I can scarcely be blamed for failing to invoke them, having not that power over words which Prof. Armstrong enjoys and with which he enlivens us.

ALFRED EGERTON.

Clarendon Laboratory, Oxford.

Artificially-induced Metamorphosis in Echinoderms.

IN 1922 (*Biol. Bulletin*, **43**, p. 210) I propounded a theory as to the mechanism of metamorphosis in sea-urchins based upon the study of dedifferentiation in the larvæ. The Echinoid pluteus responds very readily to various unfavourable conditions by dedifferentiation. Starvation, lack of oxygen, overcrowding, and poisoning with very dilute potassium cyanide or salts of heavy metals, causes the arms to shrink and eventually to be resorbed, and the body to round up and contract; at the same time the gut may dedifferentiate considerably.

I assumed that in normal development the weight of the growing Echinus rudiment would eventually carry the larva down from the optimum conditions of food and aeration near the surface, to the bottom. The conditions here, being unfavourable for the larval tissues, would cause them to begin dedifferentiation. The Echinus rudiment, not being similarly susceptible (largely, it was suggested, owing to its cells and organs not presenting so much relative surface), would then be able more successfully to compete for food materials with the larval tissues. The balance, once tilted, would swing right over in its favour, and the larval organs, once dedifferentiation had begun, would speedily be altogether resorbed.

During the last two summers, thanks to the courtesy of Prof. E. W. MacBride, who annually raises numbers of Echinus plutei to metamorphosis, I was able to put this hypothesis to experimental test.

A number of late larvæ were selected from the plunger-jars where they were being reared, and divided into five classes according to the size of their Echinus rudiment (the most advanced specimens, with incipient resorption of the tips of their arms, were rejected). A number of representatives of each class were then replaced in the plunger-jars; another similar set were placed in sea-water, changed frequently, in small vessels; and a third set were exposed to the agency chosen to induce dedifferentiation.

The most successful agency was found to be very dilute mercuric chloride, from one two-millionth to one three-millionth molar. With such solutions, the results were perfectly definite. In less than twenty-four hours, above 90 per cent. of surviving specimens (more than 70 per cent. of total number) of larvæ with moderate to large Echinus rudiments, but with no trace of arm-resorption, had completely metamorphosed or were in the middle of metamorphosis; while only 6 per cent. of the two sets of controls had done so. None of the experimental animals remained fully larval (*i.e.* without any visible alteration such as arm-resorption, etc.); while nearly 70 per cent. of the controls did so. The majority of the control specimens in the plunger-jar had not metamorphosed after ten days.

One of the artificially metamorphosed Echini lived for eight days in spite of the absence of proper food. The fact that many died in one to two days may be compared with the high mortality in artificial (thyroid-induced) metamorphosis in amphibian larvæ. Doubtless, attention to precise strength of solution and length of exposure would (again as in Amphibia) much reduce the mortality.

Further, just as high doses of thyroid given to very small tadpoles give disharmonic results in metamorphosis (resorption of tail and gill system before proper limb size can be attained), so here larval dedifferentiation in stages when the Echinus rudiment was small (about half its final larval diameter) produced disharmonic metamorphosis, the result being a mere spherical lump with no or very slight indications of tube-feet, etc.

The fact that metamorphosis can be precociously caused by inducing larval dedifferentiation is presumptive evidence that larval dedifferentiation is the primary cause of metamorphosis in Nature. At any rate, the criticism (Pérez, *Année Biol.*, 4 (pt. 2), p. 16; 1923) that since dedifferentiation is a pathological phenomenon, it therefore can have nothing to do with a normal process like metamorphosis, is shown to be without foundation. So far as I am aware, this is the first case of experimentally-altered time of metamorphosis in any group of marine invertebrates, the recorded cases being confined to Amphibia, Tunicates, and Insects.

Golgi Bodies in Plant Cells.

The interesting letter of Prof. Bose, in Nature of Dec. 3, on the Golgi apparatus of plant cells, may serve us as reason for discussing shortly the present position of our knowledge of this branch of cytology. The last ten years' work has enabled animal cytologists to show that the classic Golgi apparatus of nerve cells is a highly specialised structure, and that the true primitive Golgi body is in the form of a chromophile (osmiophile, argentophile) cortex and a chromophobe medulla, the whole usually granular in nature, except when the various elements form a close mass around the centrosome, in a juxta-nuclear position. In oogenesis these granules usually multiply rapidly and their centres become vacuolated and occupied by fatty materials forming the vitellus of the egg. In gland secretion the same phenomenon often happens. In spermatogenesis, in all animals investigated, the Golgi bodies secrete a bead which becomes attached to the nucleus to form the acrosome.

Now in plant cells, Guilliermond and his school have homologised the well-known plant canalicular system, with the net-like Golgi apparatus of nerve cells. The two structures superficially resemble each other. Moreover, as Guilliermond (and now Prof. Bose) has shown, this canalicular system in plants sometimes has the power of reducing silver, and osmic acid, as has the Golgi apparatus of nerve and other animal cells.

Recently Parat has extended the vacuolar conception of the plant 'Golgi apparatus' to animal cells, and has claimed that the vacuoles in eggs, first described, I believe, by Dr. Ludford and myself, and more recently investigated, among others, by Dr. Rodgers Brambell and Miss Shana King, and the vacuoles in gland and other cells (Ludford, Nassonow, Bowen), are the true Golgi apparatus, and homologous with the plant canalicular system. The Russian (Nassonow), the American (Bowen), and the Belgian (Duesberg), and the leading English workers, all seem to regard the cortex of the animal vacuole as the homologue of the nerve cell Golgi apparatus. The vacuole is usually regarded either as the derivative (English school) or the associate of the true Golgi cortex (osmiophile, argentophile). To the non-cytologist this can be explained by thinking of the intracellular granule as an orange. British workers regard the skin as the homologue of the nerve cell Golgi apparatus, its contents as the derivative of the cortex. Parat and Guilliermond would regard the inside as the true Golgi apparatus, and the cortex—and here they fall—as a modified mitochondrial structure!

Amidst all these discussions, Dr. Charles Walker provides curious relief, by waking up nearly thirty years after Golgi discovered this intra-cellular organella, and claiming that this structure, which can be seen *intra vitam*, is merely an artefact. Be it noted that Dr. Walker (*Proc. Roy. Soc.*, 101, 1927) does not quote the botanist, Löwschin, who previously 'showed,' about twelve years ago, that one could manufacture mitochondria *which even divided*, by mixtures of different lecithin, albumen, and salt solutions.

Löwschin's papers are rarely quoted nowadays, and deserved better treatment from Dr. Walker. Curiously enough, Parat, exponent of the vacuolar Golgi apparatus, quotes the paper of Moore and Walker on mammalian spermatogenesis as evidence for the veracity of his theory! It was really Moore and Walker who discovered the "Golgi apparatus" in animal spermatogenesis!

Now Prof. Bose, following Guilliermond and his school, has demonstrated the canalicular system in mushroom cells. Like Guilliermond, he calls these canaliculi the Golgi apparatus. For years the work of Guilliermond's school has proved an embarrassment to the zoological cytologist. We could not but believe that bodies, so universal in animal cells (as universal as the nucleus itself), would not have real prototypes in the plant cells. Parat's rocket-like flash across the cytological sky also proved a temporary embarrassment, and has put several promising men on the wrong track.

Now, however, the recent paper by Bowen comes as a relief from the confusion of French cytology. Bowen (*Biol. Bull.*, 53, 1927) claims that there are *three* categories of cell inclusions in plant cells, *besides the* *canaliculi*: Structures resembling the invertebrate Golgi bodies; secondly, the well-known plastids; and thirdly, the mitochondria. Bowen gets the canaliculi, too. Moreover, and this is crucial, Bowen shows that in mosses his supposed Golgi bodies form the acrosome of the sperm *as in animals*.

Now, in view of Bowen's work, I feel that Prof. Bose's claim that the mushroom cell canaliculi are Golgi bodies, must be rejected. I believe that until Prof. Bose and other such workers follow these bodies through the life cycle of the plants they are studying, and demonstrate what they do in gametogenesis and in the general cell life of the plant, that such work as published by Prof. Bose is a waste of time. If Prof. Bose expects other cytologists to accept the view that what reduces silver and osmium in the cell must be Golgi bodies, he is much mistaken.

The Density necessary to produce the Nebulium Spectrum.

THE chief lines of the nebular spectrum have been identified by I. S. Bowen with forbidden transitions in the atoms of singly ionised nitrogen and singly and doubly ionised oxygen (NATURE, 120, 473; Oct. 1, 1927). The life of an atom in the metastable state is very long compared to that of the other excited states, and the transfer to another state is accomplished by collisions of the second kind. Bowen argues that in the nebulæ, the density being extremely low and hence a long interval of time between impacts, the atoms in metastable states would return to normal states spontaneously with the emission of radiation. From spectroscopic data he has computed the frequency and frequency differences for N II, O II, and O III, and finds agreements with the chief nebular lines. A. Fowler has since computed the frequency differences, using data not available to Bowen, and finds even better agreement with the nebular lines (NATURE, 120, 582, 617; 1927).

It remains to be seen whether a nebular spectrum can be produced when the density of a mixture of oxygen and nitrogen becomes small enough. The production of densities in the laboratory comparable with those in the nebulæ seems to be impossible with the present technique, and it is necessary to look to celestial phenomena in which the predominating physical change is that of decreasing density. The novæ offer just such an example, for in these objects there is apparently the expulsion of a shell of gas, and at some time in the life of this shell there originates from it the characteristic lines of the nebular spectrum.

To obtain the density of the shell of gas when it reaches the nebular stage it is necessary to know the original density and radius of the shell, which is probably the atmosphere of the star, the velocity of the shell, and the interval from outburst to the nebular stage. These data are available only in the case of Nova Aquilæ 3, which had a spectrum of type A and an absolute magnitude of +2·7 before outburst. This indicates that the star belonged to the main sequence and, hence, one may make a good estimate of its radius and of the density of its atmosphere, about 6×10^5 km. and 10^{-9} grams per c.c., respectively. The velocity corresponding to a displacement of half of the width of the emission lines is taken as the rate of expansion of the shell. For Nova Aquilæ 3 this is about 1700 km./sec. (Hubble and Duncan, *Astroph. Jour.*, 66, 59; 1927.) The N_1, N_2 lines were recognised in the spectrum of the nova about nineteen days after the outburst. Assuming that the shell was moving out with a constant thickness, the density at the time of the appearance of the nebular spectrum is about 10^{-17} grams per c.c. This density compares well with the mean densities of from 10^{-18} to 10^{-20} grams per c.c. obtained for the nebulæ.

For other novæ the densities in the shells at the time of nebular stage can be obtained in terms of the original densities and radii of the shells. The results for nine novæ are as follows:

Nova.	Density.
Nova Aurigæ . .	$3·2 \times 10^{-20} \rho_0 r_0^2$ grams/c.c.
Nova Geminorum 1 .	7·7
Nova Persei 2 . .	2·2
Nova Lacertæ . .	2·3
Nova Geminorum 2 .	8·5
Nova Aquilæ 3 . .	12·7
Nova Cygni 3 . .	5·5
Nova Ophiuchi . .	2·4
Nova Pictoris . .	1·3

ρ_0 = original density, r_0 = original radius.

It is rather surprising that there should be such little variation in the coefficients of $\rho_0 r_0^2$. The constancy would seem to indicate that the novæ originate from stars of similar physical conditions and that there is a limiting density above which the conditions are unfavourable for the production of the nebular spectrum.

Until more is known of the pre-nova history, the objects will have to be treated statistically. Assuming that the original stars belong to the main sequence, and again using the density 10^{-9} grams per c.c. and the radius 6×10^5 km., the mean density at which the nebular spectrum appears is $1·8 \times 10^{-17}$ grams per c.c.

Amendments to the International Rules of Zoological Nomenclature.

UPON unanimous recommendation by the International Commission on Zoological Nomenclature, the International Zoological Congress, which met at Budapest, Hungary, Sept. 4-9, 1927, adopted a very important amendment to Article 25 (Law of Priority), which makes this Article, as amended, read as follows (*italicised type represents the amendments*; Roman type represents the old wording):

Article 25.—The valid name of a genus or species can be only that name under which it was first designated on the condition:

(*a*) That (*prior to January 1, 1931*) this name was published and accompanied by an indication, or a definition, or a description; and

(*b*) That the author has applied the principles of binary nomenclature.

(*c*) *But no generic name nor specific name published after December 31, 1930, shall have any status of availability (hence also of validity) under the Rules, unless and until it is published either*

(1) *With a summary of characters (seu diagnosis; seu definition; seu condensed description) which differentiate or distinguish the genus or the species from other genera or species;*

(2) *Or with a definite bibliographic reference to such summary of characters (seu diagnosis; seu definition; seu condensed description). And further,*

(3) *In the case of a generic name, with the definite unambiguous designation of the type species (seu genotype; seu autogenotype; seu orthotype).*

The purpose of this amendment is to inhibit two of the most important factors which heretofore have produced confusion in scientific names. The date, Jan. 1, 1931, was selected (instead of making the amendment immediately effective) in order to give authors ample opportunity to accommodate themselves to the new rule.

The Commission unanimously adopted the following resolution:

(*a*) It is requested that an author who publishes a name as new shall definitely state that it is new, that this be stated in only one (*i.e.* in the first) publication, and that the date of publication be not added to the name in its first publication.

(*b*) It is requested that an author who *quotes* a generic name, or a specific name, or a subspecific name, shall add at least once the author and year of publication of the quoted name or a full bibliographic reference.

The foregoing resolution was adopted in order to inhibit the confusion which has frequently resulted from the fact that authors have occasionally published a given name as 'new' in two to five or more different articles of different dates—up to five years in exceptional cases.

The three propositions submitted by Dr. Franz Poche, of Vienna, failed to receive the necessary number of votes in Commission to permit of their being recommended to the Congress. Out of a possible 18 votes for each proposition, Poche's proposition I. received 9 votes, II. received 6 votes, and III. received 7 votes.

Zoological, medical, and veterinary journals throughout the world are requested to give to the foregoing the widest possible publicity in order to avoid confusion and misunderstanding.

Salivary Secretions of Blood-sucking Insects in Relation to Blood Coagulation.

MOST blood-sucking insects at the time of biting inject into their host an irritant which causes a skin reaction, generally a wheal, more or less conspicuous and itching in relation to the habituation of the host to the particular parasite. Although these injections are of such great importance in the transmission of disease, their purpose has in no case been properly elucidated hitherto. Macloskie forty years ago suggested that the salivary secretion of mosquitoes prevents the blood from clotting on the way to the stomach, but the work of Nuttall and Shipley (1903), and of Schaudinn (1904), threw doubt on this theory. Cornwall and Patton (1914) proved the presence of an anticoagulin in the salivary glands of several blood-sucking insects and ticks, and also showed that a neutralising coagulant enzyme sometimes existed in the stomach.

Dr. H. M. O. Lester, of this Tsetse Investigation, has found that the tsetse-flies, Glossina, have both an anticoagulin in the salivary secretion and a coagulin in the mesenteron, and, after studying the behaviour of these enzymes *in vitro*, has come to the conclusion that their influence on the coagulation of blood is similar to that of antikinase and kinase respectively. The anticoagulin thus differs from the anticoagulant enzyme of the leech, Hirudin, which is said to be an anti-thrombin.

We have proved that Macloskie's theory, if applied to the tsetse-fly, is correct. The entire salivary glands of *G. tachinoides* may be removed by a very simple operation without killing the fly and often without causing appreciable shock. Flies from which the glands are thus removed draw blood normally for a time, causing no wheal on the most susceptible skin, and may survive for long. There is never any regeneration of the glands. One fly lived for 58 days, taking 26 meals of human blood and producing 4 healthy larvæ, while others survived to 14 days. Sooner or later the flies choke, or sometimes get convulsions, and can no longer draw blood. It is then found that the lumen of the proboscis and the œsophagus are occluded by clot, and generally the capacious crop is also full of firmly clotted blood. In the case of the tsetse-fly, therefore, the injection of salivary secretion into the host is not a necessary preliminary to feeding but rather in the nature of an accident, because the secretion mixes with the indrawn blood at the very tip of the proboscis, so that a certain amount inevitably escapes into the tissues of the host.

The amount of secretion mixed with the blood is enough to delay the coagulation of mammalian blood for 2-3 hours at least, but the coagulin of the mesenteron is so powerful that in a matter of seconds it has neutralised the anticoagulin and formed a small clot at the posterior end of the meal. The main function of this clot appears to be that it puts a brake on to the fluid meal and holds it in the proper region of the gut while digestion begins.

The Thermal State of the Earth's Crust.

THE product of the rate of increase of temperature with depth in the earth's crust into the thermal conductivity of the surface rocks gives the rate of loss of heat from the interior. When allowance is made for the residual effects of the original heat, this gives a most important datum concerning the rate of generation of heat below, and hence, if the radioactivity of the rocks is known, to an estimate of the thickness of the radioactive layer. Hitherto it has been good enough, in discussions of this problem, to adopt mean values of the temperature gradient, the conductivity, and the radioactivity. It has now, however, become worth while to allow for variation of conductivity with depth, and to attend more to details in the vertical distribution of radioactive matter. When this is done as well as is at present possible, the agreement of the results with those obtained from the study of near earthquakes is practically perfect (*Gerlands Beiträge z. Geophysik*, **18**, 1-29; 1927).

The next step towards understanding the earth's thermal state is to find out why the observed temperature gradient varies from place to place; the mean for North America, for example, is substantially less than for Europe. This may be attributed to a different thickness of the radioactive layers, or to different percentages of radioactive matter in them. But these questions cannot be effectively discussed without an additional datum that has not yet attracted the attention of observers, namely, the conductivity of the uppermost layer (usually sedimentary). The actual temperature gradients are measured in this layer, and we cannot find the rate of conduction of heat to the surface without a knowledge of its conductivity. Conductivities of sedimentary rocks are given in some of the standard physical tables, but these refer to dried specimens, and the effective conductivity of the same rocks *in situ* is probably considerably higher on account of the part played in transferring heat by water in the interstices. Further, there is no known reason why it should not vary from place to place.

If any experimenter is willing to collect samples of the rocks from the principal borings and mines where temperature gradients have been measured, being careful to retain any moisture they may contain, and to determine their conductivities, he will achieve a great service to geophysics.

Harold Jeffreys.

St. John's College, Cambridge.

The Aston Dark Space.

Sir J. J. Thomson's comment in the November *Philosophical Magazine* upon the similarity between the non-luminous layers which cover cold surfaces in a high-frequency electrodeless discharge, and the intensely dark region within the cathode dark space and immediately adjacent to the cathode of a Geissler discharge, discovered by Dr. F. W. Aston in 1907, points to a fresh way for finding the respective contributions of positive ions and electrons to the current in the latter case. Both have the appearance of the positive ion sheaths which have recently become important through their application by Langmuir to the theory of exploring electrodes. Since there is good evidence that the fall of potential across the Aston dark space is the ionisation potential of the gas, the current density of positive ions can be calculated by inserting in Langmuir's equation for a plane collector the appropriate observed thickness of the layer, and, when compared with the total current density, this will give the required information, without, of course, affording any idea as to exactly how the electrons are produced at the metal surface.

Unfortunately, the Aston dark space can be seen in only a few gases, and the experimental data by which any theory of its origin can be tested are meagre. Langmuir's analysis does, however, explain why its thickness is independent of pressure, if the effect of collisions made by the positive ions in traversing the sheath can be neglected, and also why its thickness is approximately inversely proportional to the square root of the current density, on the assumption that the relative contributions of the two types of carriers do not depend on the total current. Somewhat similar ideas seem to have been first proposed by Prof. Güntherschulze in 1925, to explain why it does not appear in heavy gases, where it should theoretically be too thin to be seen. As regards numerical agreement, we do not feel justified in saying more at present than that the quantities involved are of the right order of magnitude, but we feel that the conception of a space-charge sheath on the cathode, separating it from the main cathode dark space, does at least partly remove the somewhat arbitrary distinction between this electrode and any other type of collector which had to be made previously.

Use of the Term 'Self-Adaptation' in Biology.

The letter from Mr. A. G. Lowndes, published in Nature of Dec. 24, raises a question of great and increasing importance. We all know that the old controversy between materialism and vitalism has entered on a new phase, and a decision is once more in the balance. It is, therefore, premature to clear our biological language of all terms savouring of vitalism, more especially as materialism has definitely failed to account for certain well-defined phenomena of development. The modern tendency is distinctly against ignoring mental phenomena, and making a sharp line of demarcation between humanity and the rest of the world of life. Biologists with a philosophic training prefer to explain unknown things in terms of the known, and nobody can deny that mental processes are much more amenable to cognition than any material processes whatever. We know what we mean by the term 'self-adaptation,' and we have no reason to exclude the animal world, or even the vegetable kingdom, from the working of a process familiar to our own experience.

Materialistic biology has had its day, and has done useful work in clearing the ground of mystical conceptions. Paracelsus, the first materialist, proclaimed man to be a chemical compound. In doing so, he killed at one blow all the demons and spirits which had encumbered the art of medicine. There is no necessity now to hug obsolete bio-chemical theories for fear that if we yield an inch to the vitalists the hosts of pandemonium will be let loose upon us. We can, therefore, give due regard to the psychological factor which, on any philosophically sound view, must be co-extensive with life.

Imperial Agricultural Research.

One may hope it will not be assumed by readers of the editorial in Nature of Oct. 15 (p. 539) that anything approaching complete failure has attended the efforts of the trustees of the Science and Industry Endowment Fund to attract post-graduate students to the biological services of the Commonwealth Government. It is true that no candidate of sufficient standing came forward for the first scholarship offered in mycology. Possibly the trustees made a mistake in insisting on first-class final honours and definite proof of capacity for research, though it will be a pity if it is found necessary to lower the standard. There are, however, quite a number of graduates at present in training abroad in other branches of work, including three in entomology, two in food preservation, two in forest products, and one (recently appointed) in plant pathology. In addition, three are gaining experience in fuel research. So far no studentships in genetics have been offered.

'Greasy' Burettes.

Burettes employed in volumetric analysis to contain standard acid usually present, after short use, a greasy appearance, and considerable inaccuracy in measurement may result from the adherence of small drops of the solution to the surface of the glass above the liquid.

The necessity for frequent cleansing with a brush may be obviated by the addition of a minute trace of saponin to the standard acid, and, provided that the amount added be very small, and the solution not unduly shaken, there need be no inconvenience due to frothing.

A burette containing decinormal hydrochloric acid, thus treated, has been in use for several weeks, without any necessity for cleansing, and the device is no doubt capable of more general application to other solutions.

New Data on Alcohol and Duration of Life.[1]

By Prof. RAYMOND PEARL and AGNES LATIMER BACON.

IN "Alcohol and Longevity" (New York: Knopf, 1926) Pearl presented life tables embracing some 5248 persons, living and dead, from the working-class population of Baltimore, divided into groups according to the extent and regularity of their alcohol consumption during life. The life tables demonstrate that, so far as could be judged by the sample of lives: "the moderate drinking of alcoholic beverages did not shorten life. On the contrary, moderate steady drinkers exhibited somewhat lower rates of mortality and greater expectation of life than did abstainers. This superiority is not great in the male moderate drinker, and may not be significant statistically. But it certainly gives no support to the almost universal belief that alcohol always shortens life, even in moderate quantities."

The purpose of the present paper is to report briefly some additional evidence bearing upon these results, which has been gained from a new and entirely independent set of data. For some time past we have been engaged in the study of the autopsy records of the Johns Hopkins Hospital. The first 7500 of the autopsy protocols have been abstracted and the information they contain has been transferred to cards for statistical study. The general statistical characteristics of this material, and the incidence of cancer in it, have already been reported by us.[2] Besides the strictly pathological records from the autopsy protocols there was also set down on each working card certain information derived from the clinical history of the patient filed in the archives of the Johns Hopkins Hospital. Among other items there was transferred to the card whatever information existed in the clinical history regarding the use of alcoholic beverages by the patient. Omitting the cases in which there was no information in the history regarding alcohol habits (of which there were 3906), and those in which the statements made on the point were so lacking in precision as to make it impossible to conclude more than that the person had at some time in life used some alcohol as a beverage (of which there were 42), we have the number of cases shown in Table I. of persons twenty years or more of age at the time of death, in which the information recorded is believed to be critically accurate.

TABLE I.

Group.	Abstainers.	Moderate Drinkers.	Heavy Drinkers.
Male white . .	239	713	418
Male coloured[3] .	85	435	340
Female white .	119	66	10
Female coloured[3]	75	95	23
Total . .	518	1309	791

There are thus 2618 persons for whom we have definite records as to alcohol consumption, on one hand, and age at death on the other hand. These persons are derived from all classes of society. They include rich and poor, labourers and loafers. As a group they are far less homogeneous than the group studied in "Alcohol and Longevity." One thing that they have in common, however, is that they died in the Johns Hopkins Hospital and were there 'autopsied.' The statements which they made as to their alcohol habits were given to the hospital physician under whose care they were, as a part of their medical history. It was information given in some sense 'under the fear of death.' They were persons who had come into the hospital because they were ill and hoped to be cured, or at least benefited by medical or surgical treatment. In such circumstances they were likely to tell the truth as they knew it regarding their alcoholic habits. Anyone who is ill and hopes to be made better, will try to be as exact as possible about a habit which both he and the physician believe may have a significant bearing upon his present state, the method of treatment to be adopted, and the prognosis. Indeed his eager desire to put the physician in possession of all the facts which may possibly have a bearing upon his case often leads to a garrulity over details which sorely tries the patience of the clinician.

The rubrics 'abstainer,' 'moderate drinker,' and 'heavy drinker,' have precisely the same meaning here as the same terms did in "Alcohol and Longevity" (see pp. 72, 73 of that book for the definitions of these terms used in classifying the material in that study and in this one).

Table II. gives the distributions of the ages at death (and autopsy) of the 2618 persons included in Table I.

As we have already pointed out in the papers cited above, a hospital population is always a selected one, and the 'autopsied' proportion represents a still further selection. But we know of no reason to suppose that any of the selective factors operating under these premises are such as, *per se*, to affect differentially the distribution of ages at death of those persons in an 'autopsied' hospital population who have been previously abstainers, as distinguished from those who have been moderate drinkers, or of these in turn from those who have been heavy drinkers.

In Table III. are given the simple biometric constants for the age distribution of Table II., the centring points used being those previously given by Miner.[4]

From the data here presented the following points are to be noted:

1. As compared with a general population, the part of an 'autopsied' population here discussed is,

as a whole, inferior in mean duration of life. This has been shown in an earlier paper (*loc. cit.*) to be true of the Johns Hopkins Hospital autopsies as a whole. In this respect, and also in the respect that the mean age at death of the females is lower, generally speaking, than that of the males (instead of higher as in the general population), the part of the autopsy material here dealt with appears to be a fair sample of the total 'autopsied' population from which it is drawn. In other words, the cases for which information is available as to alcoholic habits appear not to be sensibly differentiated in other respects from the rest of the 'autopsied' group.

Male coloured :				
Abstainers	41·30±1·12	15·34±0·79	37·14±2·17	Heavy—abstainer =3·54±1·22
Moderate drinkers	42·45±0·46	14·18±0·32	33·40±0·84	Heavy—moderate =2·39±0·66
Heavy drinkers	44·84±0·48	13·10±0·34	29·21±0·82	Moderate—abstainer =1·15±1·21
Female white :				
Abstainers	46·40±0·83	13·35±0·58	28·77±1·36	Moderate—abstainer =0·92±1·44
Moderate drinkers	47·32±1·18	14·17±0·83	29·95±1·91	Moderate—heavy =5·10±2·75
Heavy drinkers	42·22±2·48	9·73±1·47	23·05±3·65	Abstainer—heavy =4·18±2·62
Female coloured :				
Abstainers	42·67±1·04	13·38±0·74	31·35±1·89	Abstainer—moderate =1·26±1·36
Moderate drinkers	41·41±0·87	12·54±0·61	30·28±1·61	Abstainer—heavy =3·12±2·11
Heavy drinkers	39·55±1·84	12·17±1·21	30·78±3·34	Moderate—heavy =1·86±2·04

2. The coloured persons in this experience have lower mean ages at death than the corresponding groups of white persons. Again the result is in agreement with the autopsy experience as a whole, as previously reported, and with general population figures. The negro seems always to be a poorer life risk than the white, under American urban conditions.

3. There is no significant difference between abstainers and moderate drinkers, in respect of mean age at death, in any of the four groups. In two groups (male white and female coloured) the mean for the abstainers is slightly higher than that for the moderate drinkers, while in the other groups the opposite condition appears. With the exception of the male coloured group, the mean age at death of the heavy drinkers is lower than that for either abstainers or moderate drinkers.

4. What the present material shows, in short, is that in the first 34 years of operation of the Johns Hopkins Hospital, all of those patients in its experience over twenty years who came to autopsy and were known to have been moderate drinkers (as defined in "Alcohol and Longevity") died at approximately the same average age as did all of those patients over twenty years of age who came to autopsy and were known to have been total abstainers. Thus material from a totally different source, collected by entirely different persons with no possible thought of its use in the present connexion, representing a different portion of the general population, and of a high degree of critical accuracy, essentially confirms the main conclusion of the former study, embodied in "Alcohol and Longevity." *This autopsy material gives no evidence that moderate drinking shortens life.*

We intend to make detailed studies of the pathology of the different organ systems of the body in this material, classified according to drinking habits.

The Glozel Investigations.

THE report of the International Commission on Glozel appointed by the Institut d'Anthropologie, appeared on Dec. 23 as a special supplement of the *Revue Anthropologique*. It describes the investigations carried out by the Commission on the ground and the results of an examination of the objects previously found.

The Commission's verdict is unanimous, and it is unfavourable. The objects examined at Glozel cannot be regarded as ancient. M. Peyrony appends a report, in which he recants his former opinion in favour of their genuine character. The criticisms of previous visitors are fully corroborated. The Commission directs attention to the unsystematic character of the digging, to which Mr. Crawford has already referred, the haphazard excavations giving the ground the appearance of having been shelled. Dr. Morlet stated that this was due to the fact that visitors had been allowed to excavate where they pleased as a pledge of good faith, and also that the antiquities were apt to occur in veritable nests.

Two trenches were dug by the Commission, one on the east and one on the west. Nine objects in all were found, including a 'brick' with alphabetiform signs, a ceramic 'idol,' which crumbled to pieces when touched, and a stone ring. Precautions were taken to prevent tampering when the Commission was not on the ground; but it is significant that loose earth usually preluded a find. Dr. Morlet stated that this was generally the case.

The Commission came to the conclusion that the objects had been 'introduced' to the point at which they were found, and at no ancient date. It was clearly evident that a clod of earth had been taken out and replaced after the 'brick' had been inserted in the place in which it was found. Of the objects previously found, mostly from the oval pit first discovered, some may be genuine, others may be ancient, but if so there is nothing to show when they were introduced. The remainder exhibit anomalies which would be difficult to explain if they were really genuine.

It was scarcely to be expected that the champions of Glozel would take the report of the Commission lying down. Immediately on the publication of the report, says the Paris correspondent of the *Times*, in the issue of Dec. 27, MM. Salomon Reinach, Loth, and Esperandieu published a manifesto in which they compared the Commission to the Inquisition and the verdict to the condemnation of Galileo. Dr. Morlet, notwithstanding the fact that his personal sincerity and integrity had been fully endorsed by the report, has also lost no time in counter-attacking. He criticises the composition and procedure of the Commission, but his reply speedily resolves itself into an attack on MM. Begouen and Capitan, and an accusation against two other members, in one case of tampering with the ground, in the other of scratching with a penknife a stone on which a reindeer was drawn. Of this, which is in the right Glozelian manner, perhaps the less said at the present stage the better.

Although it is improbable that we have heard the last of Glozel, the resources of a laboratory, and especially an analysis of the material which is said to be evidence of cremation, from which the Commission was precluded, would no doubt deal it a final blow, but one which in the opinion of most field archæologists is unnecessary.

In *Discovery* for January, M. Salomon Reinach expounds his reasons for accepting the Glozel finds as genuine. Excepting M. Reinach's own letters in the *Times*, we believe this is the first occasion on which one of the French protagonists in the controversy has had an opportunity in England of supporting the genuineness of the discovery. On the general question, M. Reinach relies on the number of the objects found; and is of the opinion that the manufacture of these three thousand antiquities is beyond the energy and powers of any forger. The inscriptions, he maintains, present certain features, such as the absence of the letter B, which would be beyond the knowledge of any but a specialist. In his view, previous discoveries, including those of Lartet, Christy, and Piette, as well as the inscriptions from Alvao in Portugal, all lead up to those at Glozel, which should not, therefore, have come as a surprise. Apparently, the survival of the reindeer in the obscure period between the palæolithic and the neolithic is to be accepted as a fact, and its representation here not regarded as evidence against the genuine character of the discovery.

In the meantime, however, M. Dussaud, curator of the Louvre Museum, in repeating his charges against the Fradins of 'faking' the finds, argues that their number and character does not preclude the possibility of forgery. He points out that Lequeux, who is now in prison for fraud in connexion with finds from Spiennes and Morocco, produced very nearly as many. Nor was the knowledge required beyond the reach of young Fradin, for books had been lent him by M. Clément. Of the first three bricks handed to Dr. Morlet, two had been treated in the furnace which existed on the site; but this was afterwards recognised by M. Franchet, an expert in ceramics, as dating from the sixteenth century. M. Camille Jullian remains unshaken in his view that the finds are genuine, but the stock in trade of a Gallo-Roman magician. He has proceeded further with the translation of the tablets and explains the Phœnician characters as an example of the practice of using Hebrew and other foreign characters in magical formulæ.

The absence of the mouth in the human faces represented at Glozel has led P. Hippolyte-Boussac of the Institut d'Egypte to ask why this feature should frequently be absent in primitive carvings, drawings, and other representations of the human form. In *La Nature* for Dec. 15, he points out that although, according to certain views, the numerous figurines found in or near burials stood for a tutelary goddess of the tomb, and the absence of the mouth may be emblematic of the silence of death, it does not explain why that rather than any other feature should be left out. He reviews a number of examples, and in particular pictures by the aborigines of Australia in which it is omitted. These he seeks to connect with an animistic train of thought such as that which placed a Wingless Victory before the Propylæum at Athens—wingless in order that she might not leave the city. By analogy the sepulchral and other figures are represented without a mouth to prevent them from talking. Obviously, P. Boussac's suggestion has no bearing on the genuine character of the Glozel figures, and wisely he refrains from committing himself on the point.

The Development Commission.[1]

THE report recently issued by the Development Commissioners for the year ended Mar. 31, 1927, is mainly a series of summaries of work in progress at the centres of agricultural research assisted from the Development Fund, and as such is a convenient source of reference. The part relating to fisheries is much shorter, but indicates the activity in sea and other investigations. Another useful reference is the list of publications for 1926-27: (*a*) relating to researches carried out at agricultural research institutes aided from the Development Fund, (*b*) published by advisory officers, (*c*) relating to researches carried out at fisheries laboratories aided from the Development Fund. These reports indicate that the Development Commission is expected to supervise a field that includes animals, plants, soils, economics, on to the welfare of the countryside, and even provision of harbours and the widening of roads.

The Development Fund now contributes a little more than £400,000, mainly to agricultural research. That this sum, large though it be, is inadequate for its aims is evident from a perusal of the report. Fortunately, in a period of national stringency, other sources have come into being to meet the increasing demands of research. The original Development Fund required in that year an addition of £200,000, voted by Parliament, £60,000 more than the previous year. Supplementary to this is a Special Fund provided by the Corn Production Acts (Repeal) Act, 1921, by which the original fund is doubled. This was limited to a five-year period and has now ceased, and new arrangements are outlined. More recently two other sources of contributions have come into being, the Empire Marketing Board for research into problems connected with production and marketing in Great Britain and overseas, and the International Education Board established by Mr. John D. Rockefeller, Jr., in 1923.

These new sources for grants are evidently handling large sums, and their relation to the Development Fund is discussed at some length. A case given in the report, the development of the Animal Breeding Research Department at Edinburgh, illustrates the position: the Development Fund contribution was £16,000, the International Education Board gave £30,000, the Empire Marketing Board £10,000, and a generous donor £10,000. The same applies to other large research institutes, so that great post-War developments have been possible. At the same time, the whole structure seems needlessly complex, and it looks as if a large amount of energy were expended on administration and finance rather than on actual research.

The recent progress of animal research is a feature of the period of the report. The large equipment necessary has been provided from the various sources indicated. The scope of the work may be seen by the reports from some of the larger centres; at Cambridge, animal nutrition and animal pathology; at the Rowett Institute, Aberdeen, composition of pastures and the influence of iodine; at Edinburgh, animal breeding and animal diseases. On the plant side, the grants cover many investigations on nutrition, breeding, and pathology. A recent development is the study of fruit, its culture and preservation, as conducted at Long Ashton, East Malling, and other research institutes, largely assisted by the Empire Marketing Board.

The scheme for advisory officers, provided for by the Development Fund for fifteen years, is reviewed at some length (pp. 89-109). The grants to eighteen centres total about £60,000, not including special grants for equipment, etc. It is now suggested that as the centres become better staffed with county organisers, the function of the advisory officer might be better described by the term local research officer. Why not use the simple word 'adviser,' which suggests advice, and allow 'officer' to lapse, since it suggests something in the way of inspection or detection?

The grants under the heading of fisheries and harbours are only a small part of the State contributions, but they have encouraged a number of special investigations, including those on haddock, herring, and various shell-fish.

A number of smaller grants have been made for the encouragement of rural industries, as a contribution to the larger movement for development of the countryside. A review of the position points out that, with motor transport and broadcasting, village life is not so isolated as formerly; hence the need for revision of schemes. Much of the present work must be experimental, but there is need for concentration so as to bring the efforts under the control of some more centralised organisation than at present.

Supplement to NATURE

No. 3036 JANUARY 7, 1928

New Results on Cosmic Rays.[1]

By Prof. R. A. MILLIKAN and Dr. G. H. CAMERON.

THE cosmic radiation is defined as that small portion of the 'penetrating radiation' which is of cosmic origin. The main purpose of this paper is to present a preliminary report upon some very recent work which throws new light upon the properties of these extraordinary rays, and shows that still harder ones exist than had heretofore been found, rays capable of penetrating 190 feet of water, or about 16·7 feet (5 metres) of lead, before being completely absorbed.

Since doubts have been expressed so late as last summer by some of the foremost of living physicists as to whether or not there are any rays which have as yet been definitely proved to be of cosmic origin, and since up to this moment different observers of undoubted credentials, such as Swann,[2] Hoffmann,[3] Kolhörster, and ourselves differ in some cases as much as eight- or tenfold in our estimates of the intensity of the cosmic radiation if it exists, our first task will be to present very briefly the nature of the evidence up to the time of these experiments, and then to see how the new results supplement this evidence.

This procedure will have the further advantage of presenting a very beautiful illustration of the slow, step-by-step process by which most advances in science are made, each experimenter building on the past, but pushing on, if he is fortunate, a little beyond where his predecessors had gone, until presently the world finds itself in the full glory of a new conception of Nature without having been conscious of any particular instant at which the dawn came. Since the days of Greek mythology, very few discoveries have sprung full-grown out of the brain of anyone.

EARLY WORK ON COSMIC RAYS.

A starting point in the study of the very 'penetrating radiations' near the earth's surface was made in 1903 when these rays were brought to light and named by McLennan,[4] Rutherford,[5] and their collaborators, who found that the rates of discharge of electroscopes could be very markedly reduced by surrounding them with successive screens of lead several centimetres thick, thus showing that rays existed in the atmosphere capable of penetrating such thick screens, and therefore appropriately named the 'penetrating radiations.'

The next important step was taken by the Swiss physicist Gockel,[6] who in 1910 first took an enclosed electroscope in a balloon to a height of 4500 metres and found, contrary to expectation, that the radiation was higher at this altitude than at the surface, a fact which at once suggested that all of it, at least, was not of terrestrial origin, but that a part of it came into the earth's atmosphere from above, an idea which had been put forward by O. W. Richardson[7] so early as 1906.

During the next four years, Hess[8] in Austria and then Kolhörster[9] in Germany made other flights like Gockel's, checked his results and rendered them more *quantitative*, Kolhörster taking balloon readings up to 9000 metres, and finding the discharge rate decreasing slightly up to about 1000 metres and then increasing, until at 9000 metres it was some seven times as great as at the surface—more accurately, 80 ions more than at the surface, since it was this difference which he reported rather than the readings themselves.

The War put a stop for a while to further advances, but in the fall of 1921 and the spring of 1922, Millikan and Bowen[10] took the next important step by building and sending up recording electroscopes in sounding balloons to a height of nearly 10 miles—15,500 metres—more than nine-tenths of the way to the top of our atmosphere, measured by the fraction of the air left below. These flights checked the results of the European observers in indicating an increasing discharge rate up to that height, though the new observed rate was very much less than had been computed from the afore-mentioned observations up to 9000 metres; thus showing that the 'penetrating rays,' *if they came from above*, were actually more penetrating than had been supposed up to that time. Since if the rays come in from above, the ionisation inside airtight electroscopes must increase exponentially, that is, geometrically with the distance of rise toward the top of the atmosphere, these very high flights were, and are now, especially significant. They place very certain and very definite upper limits upon the absorption coefficients of the rays entering the atmosphere, if there are in fact such rays.

---

[1] Substance of an evening discourse, with additions, delivered by Prof. Millikan at Leeds, on Sept. 2, during the meeting of the British Association.

[2] Swann, *Phys. Rev.* (29, 372; 1927), finds the ionisation due to such rays on the summit of Pike's Peak to be 0·75 per c.c. per sec. per atmosphere, while we found them in the same place to be close to 5 ions.

[3] Hoffmann, *Ann. der Physik* (82, 413; 1927), finds the ionisation at sea-level 0·29 per c.c. per sec. on the assumption, taken from Kolhorster's 1926 findings (*Zeit. f. Physik*, 36, 147; 1926), that the absorption coefficient is invariant and of value $\mu H_2O = 2 \cdot 2 \times 10^{-3}$ cm.$^{-1}$. We, on the other hand (*Phys. Rev.*, 28, 851; 1926), found the absorption coefficient definitely variable (the rays therefore inhomogeneous), and the ionisation at sea-level 1·4 ions.

[4] McLennan and Burton, *Phys. Rev.*, 16, 184; 1903.

[5] Rutherford and Cooke, *Phys. Rev.*, 16, 183; 1903.

[6] Gockel, *Phys. Zeit.*, 11, 280; 1910.

[7] Richardson, NATURE, 73, 607; 74, 55; 1906.

[8] Hess, *Phys. Zeit.*, 12, 998; 1911; and 13, 1084; 1912.

[9] Kolhorster, *Phys. Zeit.*, 14, 1153; 1913; and *Verh. d. Deut. Phys. Ges.*, July 30, 1914.

[10] Millikan and Bowen, *Phys. Rev.*, 22, 198; 1923; and 27, 353; 1926.

The fact, however, that the total discharge of the electroscopes in these flights was but about one-fourth what it should have been from the absorption coefficients, computed on the cosmic ray hypothesis from the data of Hess and of Kolhörster, suggested some other cause for the phenomenon. For up to this time the increasing rate of discharge with altitude was the sole phenomenon upon which the hypothesis of rays of cosmic origin rested. But other alternatives were possible, and had indeed been suggested; such, for example, as radioactive particles of unknown origin spread through the upper regions of the atmosphere. Such an alternative could be tested definitely by making *direct measurements* of the coefficients of absorption of the penetrating rays rather than attempting to compute these coefficients as had heretofore been done, on the assumption that the rays entered the atmosphere from above. For if the rays were of radioactive origin, they would not be expected to be appreciably harder than those of the known radioactive substances such as thorium D or radium C.

The next step was taken during summer of 1923, when Kolhörster[11] in Europe and Millikan and Otis[12] in America independently made the first direct absorption measurements with materials other than the atmosphere itself—the former in Alpine glaciers and in shallow bodies of water at sea-level, the latter in thick lead screens carried to the top of Pike's Peak—for the sake of throwing new light on the possible origin of the penetrating rays.

Kolhörster reported as a result of his glacier experiments an absorption coefficient of 0·25 per metre of water, or about half that previously found, namely, 0·55, thus eliminating the discrepancy between the findings from his balloon flights and our sounding balloon experiments. He states in the paper describing this work that his experiments prove definitely the existence of gamma rays of about one-tenth the absorption coefficient of the hardest known gamma rays (4·1 per metre of water),[13] but speaks with reserve about their origin. He says, after discussing various alternatives, that "one inclines more and more of late to the view that the penetrating rays are a phenomenon the origin of which is to be sought in the cosmos."[14]

Millikan and Otis, on the other hand, concluded from their new Pike's Peak absorption data that if any of the penetrating rays which they found on the Peak were of cosmic origin they had to be more penetrating, or less strong, than corresponded even with the reduced values now found by Kolhörster, namely, 2 ions at sea-level, absorption coefficient 0·25 per metre of water. The mean coefficient of the radiation which they found on Pike's Peak was but slightly less than that of thorium D, and a large part of it was certainly of local origin. They brought to light in these experiments no new evidence for the existence of rays of cosmic origin. Indeed, up to 1925, there appears from the literature to have been no feeling of certainty in any quarter that the existence of rays of cosmic origin had been proved. The increase in ionisation in closed vessels up to nearly 10 miles was an undoubted fact, and Kolhörster's glacier experiments were favourable to the cosmic ray interpretation; but the possibilities of the radioactive contamination of a glacier are not small, nor do its irregular shape and proximity to land masses adapt it well to trustworthy absorption-coefficient measurements. Further, Hoffmann[15] in Germany, with an extraordinarily fine technique, had in 1925 pronounced against the existence of rays of cosmic origin. Also in America, Swann[16] was convinced that the work of himself and his collaborators with the ionisation in vessels at pressures up to 75 atmospheres was incompatible with the cosmic ray interpretation of the penetrating radiation.

OBSERVATIONS IN MOUNTAIN LAKES.

In 1925, however, Millikan and Cameron got unambiguous evidence from their own point of view of a penetrating radiation which had to be of cosmic origin. It was indeed weaker and more penetrating than had corresponded to preceding estimates, having an ionising power at sea-level of but 1·4 ions per c.c. per sec., an absorption coefficient which became as small as 0·18 per metre of water, and a definite spectral distribution, the longest wave-lengths found having a value, computed from A. H. Compton's formula, $\lambda = 0{\cdot}00063$ A, the shortest 0·00038 A. This last is but one-thirtieth the wave-length of the very hardest gamma rays.

These experiments consisted in sinking sealed electroscopes in deep, high-altitude, snow-fed lakes, and thus finding, to take a particular case, that the ionisation in Muir Lake (altitude 11,800 ft. or 3590 m.) decreased steadily with depth from 13·3 ions per c.c. per sec. at the surface to 3·6 ions at 60 ft. (18 m.) below the surface, below which point there was no further measurable decrease with instruments of such sensibility as were being used. *This was the first time the zero of an electroscope—the reading with all external radiations completely cut out—had been definitely determined, and the results accordingly began to show that it was possible to make with certainty determinations of the absolute amount of the penetrating radiation.*

Up to the point to which we have thus far described the experiment, it proved merely either the existence at the surface of the lake of a penetrating radiation so hard as to be able to penetrate 60 ft. (18 m.) of water before becoming completely absorbed, or else a very strange distribution of radioactivity in the water of the lake.

Next, by taking similar readings in another deep, snow-fed lake, 300 miles farther south and having an altitude 6700 ft. (2060 m.) lower, *we found a similar curve, but with each reading displaced just six feet upward.* But six feet of water was exactly the equivalent in absorbing power, where the mass absorption law holds, of the layer of atmosphere lying between the altitudes 11,800 ft. (3590 m.) and 5100 ft. (1530 m.).

This experiment, supplemented by later similar findings in other lakes, therefore proved definitely three things:

First, that the effects in Muir Lake had not been due to any radioactivity which happened to be distributed in the water in a particular way.

Second, that the source of the rays was not at all in the layer of atmosphere between the two altitudes, for this layer acted in every particular like an absorbing blanket, having precisely the absorption that it should have *if the rays came in wholly from above.*

Third, that in different localities 300 miles apart, north and south, the rays were *exactly* alike at the same altitudes.

These facts, combined with the further observation made both before and at this time, that within the limits of our observational error the rays came in equally from all directions of the sky, and supplemented finally by the facts that the observed absorption coefficient and total cosmic ray ionisation at the altitude of Muir Lake predict satisfactorily the results obtained in the 15·5 km. balloon flight, *all this constitutes pretty unambiguous evidence that the high altitude rays do not originate in our atmosphere, very certainly not in the lower nine-tenths of it, and justifies the designation 'cosmic rays,'* the most descriptive and the most appropriate name yet suggested for that portion of the penetrating rays which come in from above. We shall discuss just how unambiguous the evidence is at this moment after having presented our new results.

These represent two groups of experiments, one carried out in Bolivia in the High Andes at altitudes up to 15,400 ft. (4620 m.) in the fall of 1926, and the other in Arrowhead Lake and Gem Lake, California, in the summer of 1927.

PENETRATING RADIATION IN THE HIGH ANDES.

The experiments in the High Andes had four prime objectives as follows: (1) To see whether in lakes in the southern hemisphere the altitude-ionisation curve would coincide with that found in lakes in the northern hemisphere. This curve was particularly sensitive in the very high altitude lakes obtainable in the High Andes, and the spectral distribution found in 1925 could be more accurately tested. If the northern hemisphere and the southern hemisphere curves coincided, it would go a long way toward eliminating the possibility that the rays are generated by the incidence of high-speed beta rays on the very outer layers of our atmosphere—about the only hypothesis which could put the source of these rays in the last tenth of the air about the earth. For such beta rays would be expected to be influenced by the earth's magnetic field so as to generate stronger radiation over the poles than over the equator. In Lat. 17° S. we should be completely screened from such pole effects, particularly if we could get into suitable high altitude pockets in the mountains.

R 251

(2) To obtain further crucial tests of the C. T. R. Wilson hypothesis that these rays may be due to the integration of the effects of the impact in the earth's atmosphere of electrons endowed with many millions of volts of energy acquired in thunderstorms. Lakes in suitable pockets in the High Andes would be completely screened from such effects. Also, a comparison of the rays found in thunderstorm areas with those found in large regions like California which are comparatively free from thunderstorms might furnish check observations upon this point. (3) By determining, as outlined above, the zero readings of new electroscopes to obtain new checks on our value of the ionisation due to the cosmic rays at sea-level, a quantity upon which as yet there have been wide divergences between the results of different experimenters. (4) To get into suitable pockets or valleys in very high mountains where the rays are three or four times as intense as at sea-level, and there to make more trustworthy tests on directional effects in cosmic rays—in particular to see whether the Milky Way is more or less effective than other portions of the sky in sending these rays into the earth.

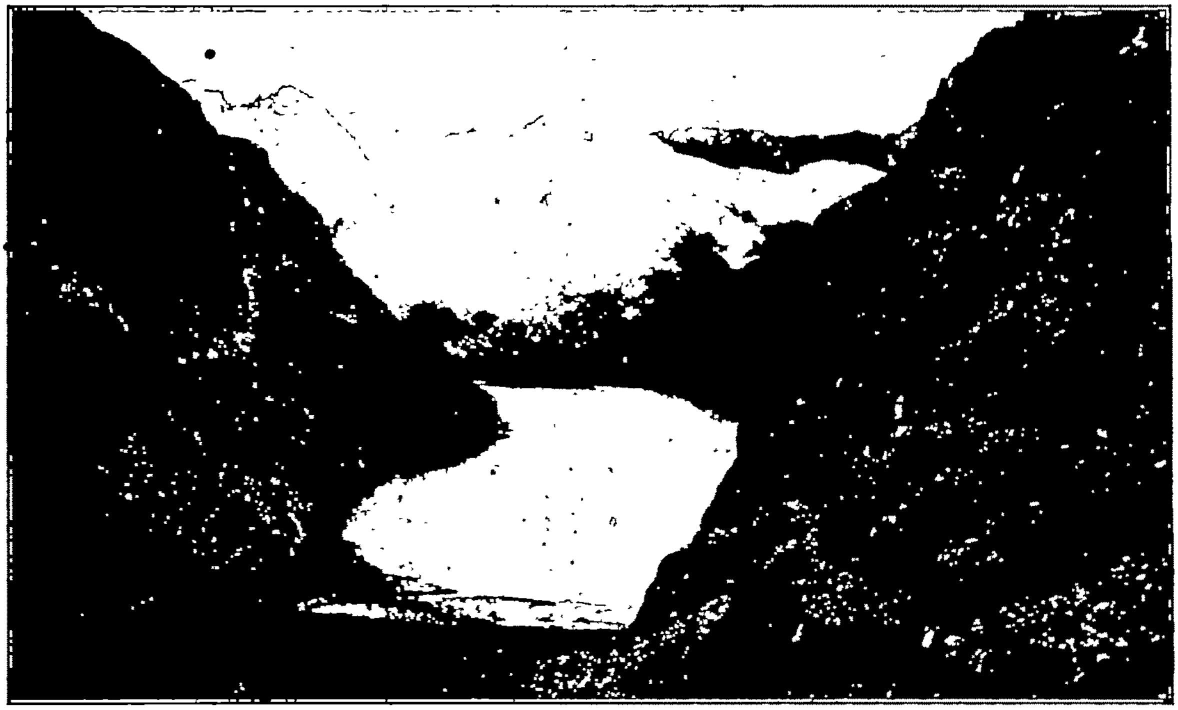

FIG. 1.—Lake Miguilla, Bolivia. Altitude, 15,000 ft. (4500 m.) about 2000 ft. long, 700 ft. wide, and 175 ft. deep.

On all these four points we obtained, despite unfortunate accidents with two of the electroscopes, satisfactory and definite information.

As to (1), we obtained on the surface of Lake Titicaca (alt. 12,540 ft. or 3822 m.) readings which corresponded very nicely with similar ones taken at Muir Lake, California. Also in Lake Miguilla, near Caracoles, Bolivia (alt. 15,000 ft. or 4500 m.), we obtained readings which fell satisfactorily on the extrapolated Muir Lake curve. If, then, there are any geographical differences in the altitude-ionisation curve, they are beyond the limits of our present observational technique.

As to (2), Lake Miguilla is a small lake surrounded on all sides by mountains several thousand feet high. It would be completely shielded from rays having their origins in thunderstorms anywhere on the earth. Further, off the coast of Central America we took a long series of readings in the wireless room on shipboard on a night on which a brilliant display of lightning was going on along the coast, and we compared the results with readings taken on the California coast, which is almost entirely free from thunderstorms, without bringing to light the slightest difference. The C. T. R. Wilson hypothesis is therefore quite definitely eliminated.

As to (3), we took the zeros of two of our electroscopes by sinking them to sufficient depths and then made an elaborate series of sea-level observations on the ship all the way from Mollendo, Peru, to Los Angeles. *We found no variation in sea-level reading with geographical position*, and but slight differences between the ionisations in different instruments, though they had volumes nearly in the ratio 1 to 2 and different sorts of walls. The mean value of the sea-level ionisation thus directly observed was but a few tenths of an ion above the mean of the sea-level cosmic ray ionisations given by the two curves of our preceding report. These curve-values were 1·4 for electroscope No. 1, and 1·6 for electroscope No. 3—mean value 1·5, which is thus checked approximately, though not yet accurately (see below), since the ionisation due to the radioactive matter in the air above the ocean must be very small. The main uncertainty in this present value 1·5 for the sea-level ionisation lies in the determination of the capacities of the electroscopes, and in uncertainties in the effect of electroscope walls. Upon the latter effect we shall make a later report.

As to (4), we took two long series of observations, each lasting three days, at an altitude of 15,400 ft. (4620 m.) in a deep valley from which the Milky Way was in sight for a period of 5 or 6 hours and then practically out of sight for another 6 hours. The value of the cosmic rays which entered our electroscopes in this valley was 3·6. *We could detect no difference at all in the value of the readings when the Milky Way was overhead and when it was out of sight.* Our error in the mean values of these readings could scarcely be more than 0·1 ion. Even if we double this estimate so as to have a wide factor of safety, we may conclude at least that the Milky Way exerts no influence upon the cosmic rays which it is yet within the power of the instruments used to detect, and that this should mean that the rays coming from the direction of the Milky Way are not 6 per cent. greater or less than are those coming from the portion of the heavens at right angles to the Milky Way. This is in agreement with our preceding less discriminating measurements, and also with recent very careful work at sea-level by Hoffmann and Steinke,[17] who can find there no directional effect in cosmic rays at all; but it is at variance with results reported by Büttner [18] and by Kolhörster.[19]

This present work was, however, done under quite as favourable conditions as have ever been used. It is very important to obtain unambiguous evidence upon this point. No entirely trustworthy conclusions about the origin of the rays can be drawn until it is settled. As yet, the case for a favoured region from which the rays come does not seem to have been established, but more sensitive tests can be made and will be made in the near future.

OBSERVATIONS IN CALIFORNIAN MOUNTAIN LAKES.

The object of the new group of experiments at Arrowhead and Gem Lakes, begun early in 1927, was to use an increased electroscope sensibility and an increased accuracy in the determination of the electroscope constants, for the sake of introducing greater precision into cosmic ray determinations and placing the whole subject upon a more strictly quantitative basis.

As already indicated, different observers are still wide apart on the absolute value of the ionisation, though a considerable group of us now find it to be between one and two ions at sea-level. This, however, can scarcely be called quantitative agreement. But this could scarcely be expected, since no observers except ourselves have thus far been able to determine the zeros of their instruments; so that all values of ionisations except ours must be regarded as estimates rather than measurements. Our own values suffer from rather large uncertainties, possibly 10 per cent., though probably less, in the determination of the capacities of our electroscopes.

As to mean absorption coefficients, Kolhörster and ourselves are now in reasonable agreement, but no one except ourselves had until very recently brought to light the inhomogeneity of the rays, though the latest results by Hoffmann and Steinke lead them to support provisionally our findings and to suggest that in the mixture of cosmic rays some may exist even harder than the hardest brought to light by us. These we found to have an absorption coefficient equal to 0·18 per metre of water, which corresponds, if computed by Compton's equations, to a wave-length 0·00038 A, or an equivalent generating potential of 32,600,000 volts. Hoffmann,[20] in order to explain his latest sea-level readings, assumes components of hardness corresponding to a wave-length, computed in the same way, of 0·00029 A, or an equivalent generating potential of 41,000,000 volts.

We began in the fall of 1926 to build new electroscopes of greater sensibility to the cosmic rays in the hope of determining the intensities of these rays more precisely and studying their *spectral distribution* more discriminatingly; in particular, we wished to test for the presence of still harder rays than could be brought to light by the sensibility of our preceding instruments; for there were theoretical reasons for suspecting that still harder rays might exist. These electroscopes will be described in detail in more technical papers. Suffice it to say here that we can now measure the capacities of our electroscopes to a few parts in a thousand (0·791 electrostatic unit is the capacity of the instrument with which the following results have been obtained), and that we are now using eight times the sensibility to cosmic rays that we have heretofore employed; so that at sea-level we have in our electroscope 11 cosmic ray ions to play with instead of 1·4, and at Muir Lake about 40 instead of 5.

[18] Buttner, *Zeit. f. Geophys.*, 2, 190; 1926.

[19] Kolhörster, *Naturwissenschaften*, 14, 936; 1926.

[20] Hoffmann. *Ann. der Phys.*, 82, 417, 1927.

In carrying out experiments with this electroscope in Gem Lake last summer, the ionisation at the surface of the lake was 33·6 per c.c. per sec., and it decreased with depth of immersion, *regularly and very smoothly, to a zero value of* 2·6. *But this asymptotic value of the ionisation–depth curve was only reached at a depth of* 164 *feet* (50 m.) instead of at about 54 feet (16·2 m.) as in our preceding 1925 Arrowhead experiments. This does not represent a discrepancy between the two sets of results. It means only that the ionisation ordinates of the curve have now been multiplied eightfold by the increased sensibility. In spite of this, the series of ionisation–depth readings taken with the new electroscope falls much more smoothly upon the curve, that is, shows less scattering, than was the case before; so that by improvements in technique the actual sensibility has been multiplied considerably more than eightfold. It is this increased sensibility and precision of measurement alone which is responsible for the fact that at depths between 54 ft. and 164 ft. ionisation is now clearly shown which was before masked by observational uncertainties.

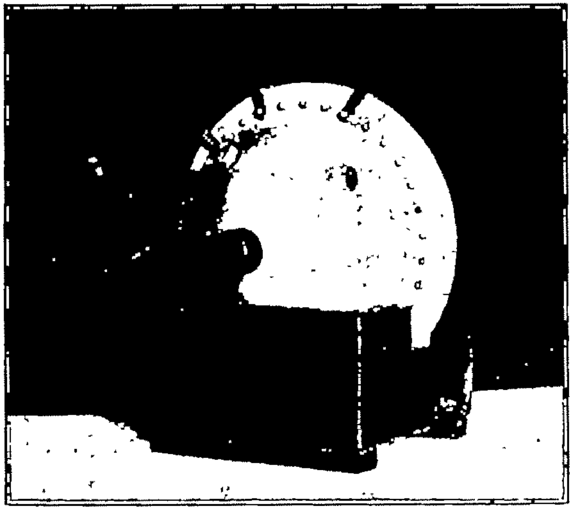

FIG. 2.—The type of electroscope sunk to depths of 164 ft. before its readings became constant at 2·6 ions/c.c./sec. Readings at surface, 33·6 ions/c.c./sec.

Taking into account the absorption of the atmosphere above Gem Lake, which is the equivalent of 7·45 metres of water, *the new experiments reveal rays so penetrating as to pass through* 57 *metres* (190 *ft.*) *of water, or* 5 *m.* (16·7 *ft.*) *of lead before being completely absorbed.*

The new curve can be analysed for spectral distribution much more reliably than has been heretofore the case; but it is very satisfying that, analysed by the method before used, the portion in the neighbourhood of the elevation of Arrowhead yields precisely the same coefficient as did the former curve in the same region, namely, 0·23 per metre of water, while *the lowest part of the curve yields the coefficients* 0·1 *per metre of water, so that we have here brought to light rays nearly twice as penetrating as those heretofore found by us.* Computed as before, the shortest wave-length is now 0·00021 A, the equivalent generating potential of which is 59,000,000 volts, very considerably higher than the estimates made by Hoffmann.

Our total curve now extends from an absorption coefficient of $\mu = 0{\cdot}25$ per metre of water to $\mu = 0{\cdot}1$, or in equivalent wave-lengths computed as heretofore, 0·00053 A to 0·00021 A, *a range of between one and two octaves.* If the computations are made by Dirac's formula,[11] which is probably more trustworthy than Compton's, the relative values do not change, but the absolute frequencies or energies are increased about 30 per cent.

The cosmic ray sea-level ionisation in this electroscope, reduced to atmospheric pressure, is the same that we published before for electroscope No. 1, namely, close to 1·4 ions per c.c. per sec., and the error here should be, for this electroscope, less than 1 per cent.

THE SOURCE OF COSMIC RAYS.

What can now be said with reference to the possible source of these extraordinary rays? Their penetrating power alone—or frequency, computed by whatever formula—obviously requires that they correspond to changes of some sort taking place within the nucleus itself, since no extra nuclear charges can possibly be associated with anything like such energies. The simplest hypothesis is that to which we directed attention in our 1925 paper, namely, that these rays are produced by direct encounters between the nuclei of atoms and high-speed electrons. It is true that the mere potential energy of separation of the electron from the nucleus is not enough in the case of the light atoms, without a larger disappearance of mass than there is as yet reason to suppose takes place. Our most energetic rays heretofore found corresponded, it will be remembered, very closely to the energy change—loss of mass—accompanying the union of four atoms of hydrogen into one atom of helium, but the new measurements give rays of practically double this energy, but still only about one-fifteenth of that to be expected from the complete transformation into radiation of the energy of separation of the positive and negative electrons; so that *there is as yet no direct experimental ground for supposing that this last sort of annihilation of mass occurs.*

---

[11] Dirac, *Proc. Roy. Soc.*, 109, 206; 1925.

If, however, there are processes widely distributed throughout the universe by which electrons become endowed with many millions of volts of energy—C. T. R. Wilson calls upon thunderstorms on the earth as one such process—then there is no difficulty in calling upon the encounters between such electrons and the nuclei of atoms, however light, to act as sources of the observed rays. We shall not here attempt to list possible causes for such high-speed electrons, but if we postulate their existence the cosmic rays follow at once. For from the best of spectroscopic evidence the astronomer now populates interstellar space with not less than one atom per cubic inch. Furthermore, from the ionised state of the calcium atoms which are found in interstellar space, Eddington [22] estimates that the temperature of space, defined by the mean kinetic energy of agitation of the atoms and electrons therein found, is about 15000° C., *i.e.* higher than the surface temperature of the sun or of that of most of the stars.

Again, no radiations of the sort here considered, if generated in the interiors of stars, could possibly get out, since they follow the mass absorption law, and according to the foregoing experiments are all absorbed in a thickness of 190 ft. of water. This thickness might be multiplied many, many fold before getting through the merest outer skin of a star. The mass equivalent of this thickness will be reached by going out in any direction to a distance of 10^8 light-years, on the assumption that space is studded with one atom per cubic inch. These considerations, if correct, indicate that the directions of the sun or the stars are not likely to differentiate themselves from other directions as sources of these rays, and all observers are agreed that the sun at least does not so differentiate itself.

If, however, high-speed electrons are postulated as a source of these rays, why not let these high-speed electrons be the rays themselves? Why assume short ether waves at all? The answer is that we know experimentally that through the photo-electric process the same energy can be interchanged without loss between ether waves and electrons. Also, according to Ellis's results, these quantum laws are followed quite as well in nuclear as in extra nuclear changes. The degradation of the energy into heat, however, takes place primarily when the energy is in the electronic carrier. In other words, the absorption coefficient of beta rays is a hundred or more times greater than that of ether waves of the same energy; so that electrons set into motion by the Compton process or otherwise, very rapidly degrade the energy when it gets into them in any locality; but its transport through space in the concentrated form (which corresponds to high penetrating power) must take place when it is in the form of ether waves.

It is therefore quite futile to postulate as the source of the observed rays the bombardment of the air in the outer tenth of our atmosphere by high-speed electrons of the same maximum energy. If such high-speed electrons could enter the top of our atmosphere in sufficient quantity, they would indeed produce just such rays as we observe; but the difficulty is *that they would have been doing so all through space*, and it would be the ether waves with their high penetrating power rather than the high-speed electrons with their relatively low penetrating power which would reach our atmosphere in quantity. It would be only in case the high-speed electrons were in the main generated relatively near us, as in the sun or nearer stars, and had not yet had space, before reaching the earth, to have their energy dissipated into heat or transformed into the more penetrating rays, that this argument would be invalid.

But *this last case is precisely the one that has been eliminated by our failure to find that the sun has any appreciable influence upon this radiation.* For if the direction of the sun stood out above other directions in the heavens as one in which high-speed beta rays were superabundant, it would, of necessity, also be a direction in which the cosmic rays were generated in abnormal abundance. It seems quite impossible then, on this theory of their origin, to limit the source of the rays to the upper tenth of our atmosphere or to any astronomically near-by regions.

COSMIC ORIGIN.

Again, the foregoing considerations as to the distance from the earth at which the rays originate apply with ever greater force to any hypothesis involving either spontaneous or induced nuclear changes not associated with electron impacts; for matter in the upper tenth of our atmosphere must upon any such hypothesis be endowed with properties entirely unlike any which matter just a little closer to us or more remote from us possesses.

---

[22] Eddington, "Stars and Atoms," p. 69 (Oxford Press, 1927).

Now while matter in remote regions of the universe may well be assumed to be endowed with properties which do not manifest themselves on earth, it would be a violation of the principle of minimum hypothesis to assume that a thin ring of matter just beyond us has properties which matter neither more remote nor more near possesses. We can see no possible way, then, of assigning to the rays any other than a cosmic origin; and if the Milky Way does not differentiate itself from other parts of the sky as a source of the rays—and our experiments thus far have failed to find any such differentiation—then *the rays must come, in the main, from beyond the Milky Way, i.e.* either from the spiral nebulæ, if these are uniformly distributed throughout the heavens, or else from 'the cloud in space.'

From the results of our 1927 experiments, we are now for the first time able to compute with a fair degree of confidence the total energy per sq. cm. per sec. that flows into the top of the earth's atmosphere in the form of the cosmic rays. It comes out $3{\cdot}1 \times 10^{-4}$ ergs cm.$^{-2}$ sec.$^{-1}$, or just one-tenth the total energy coming into the earth's atmosphere in the form of star light and heat.

Obituary.

Prof. Milton Whitney.

By the death on Nov. 11, at the age of sixty-seven years, of Milton Whitney, soil science loses one of its most striking and original personalities. His work extended over nearly forty years, and throughout the whole period he was noted for the freshness of his outlook and the novelty of his deas. He first came into prominence in 1892, when, as professor of geology and soil physics at the Maryland Agricultural College and physicist to the Experiment Station, he published an interesting paper, "Some Physical Properties of Soils in Relation to Moisture and Crop Distribution," in which he examined a number of soils of known productiveness and showed that their agricultural properties are closely related to the texture of the soil as revealed by mechanical analysis. The physical properties of the soil, especially the texture, regulate its temperature, moisture content, and air supply, or, as he called it, with the love of analogy which characterised all his writings, the 'climate' of the soil, and he argued that the significance of these physical properties in determining the distribution and yield of crops must therefore be of the same order as that of climate in the ordinary sense of the word. In short, these physical factors are the predominant factors in soil fertility. He thus broke completely away from the idea currently accepted at that time that fertility is mainly a matter of chemical composition of the soil. The American workers were prepared for this insistence on the physical properties, as W. H. King had already at Madison been carrying on important physical studies, and there were no active soil investigators in Great Britain to controvert the position even if they had wished to do so.

This and other papers marked out Whitney as a man of ideas, and when the United States Department of Agriculture set up its Soil Bureau in 1894, Whitney was put in charge. Among his early studies here was one on the tobacco soils of the United States, showing the close connexion between the quality of the crop and the texture of the soil. High quality or 'wrapper' tobacco was produced on soil containing much sand and little clay, while low quality or 'filler' tobacco was grown on heavier soils containing more clay and silt. Other crops showed similar relationships with soil composition, and Whitney regarded his thesis as so well established that, in the great soil survey of the United States then being organised, he used mechanical analysis as the basis of classification. The scheme has, in point of fact, been altered, but it served a very useful purpose.

Before long it appeared that mechanical analysis alone would not suffice to explain all the phenomena of fertility. For example, in the survey of Florida, two widely different soils, the good 'pinelands' and the barren 'hammock soils,' had the same mechanical analysis, yet obviously could not be classed together. Whitney tried electrical methods of soil moisture determination in the soil *in situ*, but without much result: he was led, however, to recognise the importance of the soil solution in the nutrition of the plant and, in conjunction with Cameron, brought out a paper in 1903 on the chemistry of the soil in relation to crop production, in which the principles of physical chemistry were for the first time applied to the soil.

The subject was so novel that most investigators were not prepared for it, and some of the deductions were so startling that they gave rise to a vigorous controversy—the first there had been in soil science for many years. The centre of it was Whitney and Cameron's statement that the soil solution, which is the proper food of plants, is of the same order of composition and concentration in all soils, and therefore all soils, fertile and infertile, are equally well supplied with plant food: fertilisers do not feed the plant, but act in some other way. The controlling factor in soil fertility was in some cases physical, but in some at least it was the presence of toxic substances in the soil. This led to the study of the organic substances in the soil by Schreiner and Shorey, and the isolation of dihydroxystearic acid and other poisonous substances from certain infertile soils.

The controversy is now over, and it is known that the soil solution does vary in composition and in concentration in different soils and in different seasons in the same soil. But the great value of Whitney's work remains unchallenged: he widened the range of the subject and enriched it with ideas and analogies which, if not themselves entirely sound, nevertheless make the investigator stop and think.

E. J. Russell.

Mr. W. C. F. Newton.

The death of Mr. W. C. F. Newton, on Dec. 22, at the age of thirty-two years, takes away a young worker of rare quality in a field that has been but sparsely cultivated in Great Britain—cytology and its bearing upon genetics. Newton was a student at the Birkbeck College, but his course was interrupted by war service (he received the Mons medal) and he did not take his degree until 1921. With a scholarship from the Department of Scientific and Industrial Research, he continued to work at the Birkbeck under Dame Helen Gwynne-Vaughan, and began to investigate the chromosomes of Galtonia, a paper on which appeared in the *Annals of Botany* for 1924.

In 1922, Bateson, who had long been on the look-out for a cytologist, invited Newton to join the staff of the John Innes Horticultural Institution, and there he continued to work. Much time was not given to him, for he had to undergo a severe operation in the summer of 1926, and was in hospital while he corrected the proofs of his paper (*Jour. Linn. Soc.*, 1927) on the chromosomes of Tulipa and allied genera. This paper contains some incidental mention of the improvements in technique he had introduced, methods of fixing and staining which are now in general use, though, as they had been freely communicated in talk, it is forgotten that they originated with Newton. Newton came back to the laboratory in 1927, and resumed his work on tetraploid hybrids, among them *Digitalis ambigua* × *purpurea* (produced by B. H. Buxton) and *Primula kewensis*. Around the latter hybrid many misconceptions had arisen, which by the perfection of his technique he succeeded in removing, finally reconciling its peculiar cytological and genetical behaviour.

Newton had not finished with Tulipa, a genus abounding with problems, providing the sort of material most apt for his thesis, that cytological relationships provide the real key to systematics. But the study of tulips has lost within a short space both Dykes, who had given years to the collection and morphological examination of the species, and now Newton, who was seeing his way to bring order out of the confusion. He was also occupied with colour inheritance in poppies and an interesting sex problem in Silene, until in the late autumn the recurrence of his malady laid him aside. But he never lost either his interest or his courage, and within a few days of his death, in a state of pitiful weakness, he would still discuss his problems and suggest the lines on which further work was needed.

Such was the man, a true *passionné* (pour faire quelquechose de grand il faut être passionné), soft-voiced and gentle, almost austere in manner until his humour broke out, but rigorous for himself and carrying his high laboratory standards into the other walks of life and learning. Death has dealt hardly with the men whom Bateson gathered round him at one time or another, and Newton bade fair to carry on in a quite different fashion that inspiration and stimulus which had so characterised his chief.

A. D. H.

MR. HENRY EDMUNDS.

HENRY EDMUNDS, who died at Hove on Nov. 18, at the age of seventy-four years, was one of the pioneers of electric lighting. He was born at Halifax in 1853. At the age of twenty-four he introduced electric lighting by Jablochkoff candles into America. He then returned to introduce the Farmer-Wallace system of electric lighting into England. The Brush Electric Lighting Co. appointed him its first engineer, and so early as 1879 he did much to popularise the Brush system of lighting in Great Britain.

In conjunction with Sir Joseph Swan, Edmunds installed incandescent lamps in H.M.S. *Inflexible* and the Atlantic liners *City of Richmond* and *Servia* in 1881, and in 1885 he became a partner in the firm of Messrs. W. T. Glover and Co., of Manchester, the cable manufacturers. He was a personal friend of Mr. T. A. Edison, and brought the first phonograph to England. An account of this invention was published in the *Times* in January 1887. He was also associated with the late Mr. Augustus Stroh in the manufacture of phonographs. Amongst electrical engineers, however, he is best known by his connexion with the cable manufacturing industry. He founded the Cable Manufacturers' Association, which is an early and successful example of co-operative working.

Edmunds was also one of the earliest of the pioneers of cycling and motoring in England. In 1898 he brought from Paris a De Dion motor tricycle and trailer, which at the time excited great public interest. It is also interesting to recall that he introduced Mr. C. S. Rolls to Mr. Royce, a meeting which led to the formation of the Rolls Royce Company. He had a very interesting personality and will be missed by many friends.

HERR JULIUS BAUMANN, deputy-director of the Verein für chemische und metallurgische Produktion in Aussig-Karlsbad and extra-ordinary professor of technical chemistry at the University of Innsbruck, died on Aug. 17. Born in Hungary in 1859, Baumann studied for a time at Prague, but soon relinquished the idea of an academic career and devoted his energies to chemical industry, in which he became recognised as one of the leading personalities in Austria.

PROF. PAUL GROTH, of the University of Munich, the well-known crystallographer and author of "Die physikalische Krystallographie," died recently at the age of eighty-five years. His discovery in 1870 of morphotropy, or change in crystalline form due to the replacement of hydrogen by other atoms or groups, was largely responsible for stimulating investigations into the structure of atoms.

WE regret to announce the following deaths:

Surgeon Rear-Admiral Sir Percy Bassett-Smith, K.C.B., C.M.G., a past president of the Royal Society of Tropical Medicine and Hygiene, on Dec. 29, aged sixty-six years.

Mr. R. B. Buckley, C.S.I., formerly chief engineer to the Government of Bengal and author of "Irrigation in India," on Dec. 19, aged eighty years.

Mr. W. H. Dines, F.R.S., distinguished for his work on the physics of the upper air, on Dec. 24, aged seventy-two years.

Mr. S. W. Fairchild, of the firm of Fairchild Brothers and Foster, manufacturing pharmaceutical chemists, who founded the Fairchild scholarships and prizes for pharmaceutical students in Great Britain and Ireland and in the United States, on Nov. 13, aged seventy-five years.

Prof. Georg Fendler, until recently chemical director of the new research institute for foodstuffs in Berlin, on Sept. 11, aged fifty-four years.

Mr. H. A. Grueber, late keeper of the Department of Coins and Medals at the British Museum and for many years honorary secretary of the Royal Numismatic Society, on Nov. 21, aged eighty-one years.

Mr. J. B. Hill, until 1922 geological adviser to the Ministry of Health and formerly of the Geological Survey of Great Britain, on Dec. 18, aged sixty-five years.

Dr. William R. Orndorff, professor of organic and physiological chemistry at Cornell University, on Nov. 1, aged sixty-five years.

Prof. Hugo Strache, director of the Institute for fuel technology at the Technische Hochschule in Vienna and a leading authority on gaseous fuels, on Nov. 4, aged sixty-two years.

News and Views.

One of the most interesting features of the Leeds meeting of the British Association was undoubtedly the evening discourse by Prof. R. A. Millikan on "Cosmic Rays," which we are privileged to publish, with additions, as a special supplement to this issue. The fact that an electroscope would gradually lose its charge even when surrounded by considerable thicknesses of metal had been known for many years, and a good deal of experimental work was done in the early days of the subject, without any very positive results, to discover the origin of this 'spontaneous' ionisation. The difficulty is, of course, that radio-active materials are very widely disseminated in minute quantities, and the possible presence of such material in the electroscope walls, and in the plates used to screen the instrument, was a continual source of uncertainty and confusion. The first advance in the subject was secured when Gockel made balloon ascents with an enclosed electroscope in 1910, and found that the rate of discharge became appreciably greater as the altitude increased, thus suggesting that part of the effect, at any rate, was due to penetrating radiation coming through the atmosphere from extra-terrestrial sources. These results were confirmed and extended by Millikan and Bowen, among others, in 1921. In his more recent experiments, Millikan, who has pursued the subject with all his well-known vigour and skill, has been using, as his absorbing material, the water of snow-fed lakes in the high mountains of California and Bolivia, material which he finds to be exceptionally free from radioactive contamination.

By sinking electroscopes into the depths of these mountain lakes, Millikan is able to measure not only the absorbability of the radiation in water, but also the actual fraction of the whole effect which is due to radiation from extra-terrestrial sources. This amounts to 1·4 ions per c.c. per second at sea-level. From the nature of the absorption curves he is able to analyse, more or less satisfactorily, the extra-terrestrial or cosmic radiation, and from the absorption coefficients, assuming that the ordinary relation between wave-length and absorption holds in this part of the spectrum, to deduce the wave-lengths of the cosmic rays. According to Millikan's latest results, the most penetrating of the cosmic rays has a wave-length of only 0·00021 A, a wave-length far shorter than the shortest of the γ-radiations from any known radioactive material, and corresponding to a generating potential of nearly sixty million volts. By working at different times of day and in two hemispheres, Millikan has shown that the radiation is not due to the impact of high-speed electrons on the outer layers of the atmosphere; neither does it come from any particular direction in space. Its intensity is the same no matter to what portion of the heavens the electroscope is exposed. It is not in the stars that we must look for its origin; its birthplace is either in the great nebulæ, or in that very rarefied matter which pervades all space. Even so, its existence seems to postulate phenomena unknown terrestrially. The excitation voltage demanded, sixty million, is not only far greater than anything possible in the extranuclear system of the atom: it is also far greater than the voltages we are accustomed to associate with the nucleus itself, which are generally of the order of two or three million volts.

Millikan points out that the most penetrating of the rays which he has so far detected has only about one-fifteenth of the energy to be expected from the mutual annihilation of an electron and a proton, and thinks that *as yet* the cosmic rays do not provide direct evidence of the transformation of matter into radiation in outer space. On the other hand, much of the radiation is of the quality which might be expected from the conversion into radiation of the mass which is lost when four hydrogen atoms condense to form an atom of helium. These results are full of interest, and it seems as if here again we have a subject where a careful watch on Nature's laboratories in the heavens might enable us to supplement the obvious deficiencies of our own.

The list of New Year honours includes the names of the following men of science and others associated with scientific work:—*Baronet*: Major-General Sir Richard Havelock Charles, Sergeant Surgeon to H.M. the King, a past president of the Royal Society of Tropical Medicine and Hygiene. *K.C.V.O.*: Sir Frank Baines, until lately Director of Works, H.M. Office of Works. *Knights*: Prof. Jahangir Cooverjee Coyajee, professor of political economy and philosophy in the Presidency College at Calcutta; Mr. F. G. Hallett, Secretary of the Joint Examining Board, Royal College of Physicians of London and Royal College of Surgeons of England; Brigadier-General H. B. Hartley, fellow and tutor of Balliol College, Oxford, and member of the Chemical Warfare Committee; Dr. E. H. Pascoe, Director of the Geological Survey of India; Principal C. Grant Robertson, Vice-Chancellor and Principal of the University of Birmingham; Dr. T. E. Stanton, Superintendent of the Engineering Department, National Physical Laboratory; Mr. A. E. Aspinall, secretary of the Imperial College of Tropical Agriculture, Trinidad. *C.M.G.*: Major R. G. Archibald, Director of the Wellcome Tropical Research Laboratories, Khartum; Mr. O. T. Faulkner, Director of Agriculture, Nigeria.

Sir Dawson Williams is retiring this month from the editorship of the *British Medical Journal*, after completing his thirtieth year in that office and seventeen years previously in the editorial department of the journal. He is being succeeded by Dr. N. G. Horner, who has been assistant editor for the past eleven years and previously served on the staff of the *Lancet* in a similar capacity. The *British Medical Journal* was first issued as the weekly organ of the Association in 1857, and it has continuously grown in importance with the Association, which is now in its ninety-sixth year and has a membership of nearly 34,000. The Association was established for the promotion of the medical and allied sciences and the maintenance of the honour and interests of the medical profession. Its organisation and its journal show what can be done to foster fellowship and promote progress among members of a profession widely scattered and with diverse interests. Sir Dawson Williams had to steer his bark through some troubled seas caused by the introduction of the National Insurance scheme and the War, and the success with which he did so is represented in the high character of the contents of the journal and the continued progress of the Association. He goes into retirement with most cordial good wishes of all who know his work and influence.

An important step towards developing an efficient organisation for the scientific study of the difficulties besetting primary industries has been taken by the Commonwealth Council for Scientific and Industrial Research. It has been decided to establish a strong entomological section which, as was announced in our issue of Nov. 26 last, will be under the control of Dr. R. J. Tillyard, at present Assistant-Director of the Cawthron Institute, New Zealand. Dr. Tillyard will commence his new duties at the beginning of March. It is proposed to erect central laboratories and insectaries at Canberra and sub-stations in various parts of the continent. Provision will be made not only for a permanent supporting staff, but also for post-graduate students who may desire to specialise in entomological research work under Dr. Tillyard's guidance.

It is estimated that insect pests cost Australia as much as £10,000,000 in a bad year, the blow-fly alone, in its ravages on sheep, accounting for £4,000,000. Attention will largely be concentrated upon the problem of blow-fly control by means of parasites, but at the same time active work will be carried on to secure control of buffalo fly (Lyperosia), lucerne flea (Smynthurus), thrips, and underground grass grub (Oncopera). Noxious weeds also cost Australia large sums annually. The success which is attending the attempt to eradicate prickly pear by means of Dactylopius, Cactoblastis, and other insects, encourages the hope that St. John's Wort, Skeleton weed, Paterson's curse, and other widely spread plants, may be brought under control. The necessity for hastening prickly pear eradication is being recognised, since there are numerous native insects which may parasitise the beneficial ones, particularly the valuable Cactoblastis, and reduce their efficiency. St. John's Wort covers nearly a quarter of a million acres of splendid land in the north-west of Victoria and is rapidly spreading into the fertile areas of Gippsland. A sub-station to deal with it will be established shortly. It is hoped that close association with the Imperial Bureau of Entomology, with Rothamsted, and also with the Cawthron Institute, will be maintained in all this work.

The amount of energy that is duplicated, and, in so far as duplication is unnecessary, therefore wasted, in the preparation of annual analytic indexes to biological literature, has long been the subject of protest, suggestion, and not very effective remedial experiment. It is interesting, and some may find it hopeful, to learn that the International Institute of Intellectual Co-operation, which is working under the League of Nations, is making a fresh attempt to introduce order and co-ordination. A meeting of editors of the chief biological bibliographies was convened at the Institute in Paris last April, and passed several resolutions which have recently been approved by the assembly of the League of Nations. The chief recommendations are these: That editors of journals publishing original work in biology should supply, through a central organisation, enough copies of each paper for distribution to the bibliographic bodies concerned. That an author's abstract, averaging from three to five per cent. of the original paper, should be published with each paper. For purposes of distribution or exchange of scientific contributions, the bibliographic publications must be classed, and the following groups are suggested: General biology; zoology; systematic zoology; botany; systematic botany; genetics; physiology; anatomy and embryology; microbiology and parasitology.

The scheme was sketched out when only one number of *Biological Abstracts* had appeared, and its importance could not be estimated. This may entail modifications, but meanwhile the Institute of Intellectual Co-operation desires to have the views of biologists, and in particular of the editors of bibliographic journals. Suggestions, which will be welcomed, should be addressed to the Director of the Institute, 2 Rue de Montpensier (Palais-Royal), Paris, I. The most valuable proposal, if it can be carried out, is the distribution of papers to the relevant bodies. The difficulty of seeing the literature is the greatest obstacle to all bibliography. The compulsion of authors to furnish abstracts will, if enforced, be splendid—for the authors. Many authors cannot produce abstracts of their own papers, and often succeed in giving marvellously little information. But *Biological Abstracts*, if it continues, will give us more than we need in this direction, at least for readers of English. That points to two difficulties. It is sometimes suggested that every scientific worker should be able to read English, French, German, Italian, and Spanish; but how many can? *Rivistas*, *Revues*, and *Berichte* will still be called for. Then the bulk is so enormous that special subjects will in self-defence organise their own bibliographies; though perhaps they would do better to produce analytic indexes such as the *Zoological Record*. Again, many periodicals would collapse did they not give reviews and abstracts of recent publications. The question of bibliography is part of the larger question of scientific publication, and those who discuss it must take human nature largely into account.

With great enthusiasm and assiduity Mr. W. Rodier continues to urge the adoption of his method of exterminating rats, rabbits, and other polygamous pests. In a recent circular he cites the success which has attended the method, now widely adopted for the increase of wild stock, of killing males and sparing all females, and suggests that the reverse process, killing females and sparing males, will have the opposite result of reducing the stock. It is obvious that the slaughter of females must reduce progeny, but it cannot be assumed that the sparing of the males will hasten the process under ordinary conditions. Nor is it evident that where pests have increased in spite of the killing of both sexes, the sparing of the males would have transformed the increase into a decrease. The Rodier method can be successful only where the numbers of females are so reduced relatively to the males that male competition interferes with successful breeding. This is likely to take place only in delimited areas where the immigration of females from outside and the emigration of males can be prevented, and where, moreover, intensive trapping has reduced the sex proportions to the requisite critical point of interference. These conditions are not easily attained.

THE Central Cotton Committee of Russia has published a volume in Russian on "Locusts and Grasshoppers," by B. P. Uvarov (Library of Cotton Industry, vol. 8, Moscow, 1927; pp. 305). The book presents a comprehensive account of the morphology, anatomy, physiology, development, and behaviour of locusts and grasshoppers in general; further, ecology, natural enemies, and causes of periodic mass appearances and of migrations of the insects in question are discussed in detail. Description and critical discussion of technique and organisation for the control of locusts and grasshoppers conclude the general part of the book, and succeeding chapters are devoted to a discussion of all the more important Russian species, with particular reference to their ecology and bionomics. A list of more than 300 references to literature, in ten different languages, is appended. We understand that an enlarged English edition of the book is to be published shortly in Great Britain.

MARCONI short wave-beam services are now in operation to Rio de Janeiro and Buenos Aires. Brazil and the Argentine are thus in direct communication with London. The beam service operates both to and from Rio, but at present Buenos Aires has no beam aerials and so it has only a one-way service. In the near future, however, the two-way beam service will be completed. The success of the beam services is now assured. The Australian Prime Minister has said that they have attracted 45 per cent. of the Pacific Cable Co.'s traffic from Australia alone, as well as what they have taken from other cable routes. During the week ending Dec. 3, the total number of words carried over the four British Empire circuits was at the rate of considerably more than 40 million words a year. The beam services with New York, Rio, and Buenos Aires are expected to be equally great. The beam transmitting stations for the North and South American services are situated at Dorchester and are operated by 'remote control' by the signalling keys in London. The receiving station is at Somerton, about thirty miles from Dorchester. These services are normally worked at about 150 words per minute, but much higher speeds can be attained. The only limit to the speed appears to be that introduced by the recording apparatus. It is possible to vary the width of the beam. In this way the Rio stations can handle traffic from Paris and Berlin as well as London. Receiving aerials are now being built near Paris, but they have not yet been begun in Germany. When the final arrangements are completed there will be seven Marconi beam services operated from Dorchester and Somerton: two to the United States, two to South America, two to Japan and the Far East, and one to Egypt.

THE Society for Experimental Biology held its London meeting at the Imperial College of Science on Dec. 21–22. The very full programme of papers and demonstrations included a symposium on certain aspects of tissue culture, in which Dr. G. P. Wright, Mrs. B. Holmes, Dr. H. B. Fell, and Dr. Canti took part. In connexion with this, microscopic demonstrations were given by Miss S. F. Cox on the effects of X-rays of different wave-lengths on mitosis in tissue cultures, by Dr. Fell on the development of the isolated otocyst of the chick embryo, by Mr. F. G. Spear on the effects of low temperature upon mitosis *in vitro*, and by Miss D. H. Strangeways on monocytes and fibroblasts in tissue culture. Profs. MacBride and Huxley discussed problems in connexion with the metamorphosis of echinoderm larvæ and dedifferentiation under certain conditions; Capt. Diver gave an unusual study of the variation in webs of the spider *Epeira diadema* and another species. Dr. C. M. Yonge described the mechanism of feeding and digestion in Septibranchs, including deep-sea forms, and Dr. G. C. Robson discussed the variation of the radula in the Octopus and in Peristerna. Mr. E. A. Spaul described further experiments on the comparative quantitative effects of thyroid and pituitary in producing metamorphosis in Amphibians. Mr. J. T. Cunningham described experiments on the effects of ligature of the vas deferens and the vasa efferentia in mammals. Miss M. A. Tazelaar gave an account of experiments with eggs of the frog and the hen, in which the two poles or the two sides of the young embryo were subjected to different temperatures. Mr. R. Snow described the transmission of inhibition to bud growth through dead stretches of stem, while papers were presented by Dr. A. Walton and Mr. J. A. Hammond on the mechanism of impregnation and spermatozoan movement in the rabbit and the experimental production of small litters. The meetings concluded with the exhibition in the Imperial Institute cinema of a remarkable film showing the growth, division, and other activities of living cells in a tissue culture from the periosteum of the chick embryo, by Dr. Canti. The behaviour of cells in a culture of Jensen's rat sarcoma was also shown, as well as the effects of irradiation on the living cells. The next meeting of the Society will probably be held at Oxford in April.

IN consequence of the increased activity in oil-field investigation in Australia, and following the appointment of Dr. W. G. Woolnough as Commonwealth geological adviser, the services of Mr. Frederick Chapman, of the National Museum, have been lent to the Commonwealth for a year as Government palæontologist.

PROF. E. W. BROWN, professor of mathematics in Yale University, New Haven, has been elected an associate of the Royal Academy of Belgium, and M. Armand Renier, director of the geological services of Belgium, and Prof. Lucien Hauman, professor of botany in the University of Brussels, have been elected *correspondants* of the Academy.

THE Ministry of Health has issued a memorandum (Memo. 122 A/T.) showing under various heads the cost per patient per week at certain residential institutions for the treatment of tuberculosis during the year ended Mar. 31, 1927. A mass of information has been collected, analysed, and tabulated which should be of the greatest value to authorities and other bodies who administer tuberculosis sanatoria.

IN preparation for the meeting of the International Commission on Illumination in America in September next, the technical committees of the Commission met at Bellagio, Lake Como, in September 1927, to discuss forty-six papers which had been prepared. The problems of eliminating glare in industrial lighting, motor headlights, street lighting, and signal glasses received much attention. Copies of a brief report of the meetings can be obtained from the Secretary of the Commission at the National Physical Laboratory, Teddington.

THE annual report for 1926–27 and *Proceedings* of the first session of the Merseyside Aquarium Society has been received. This Society was formed in Sept. 1926 with the object of helping those interested in aquatic life. Several good lectures have been given and excursions organised, the president being Dr. James Johnstone, professor of oceanography in the University of Liverpool. We note that "negotiations are at present being conducted by a sub-committee with a view to space being reserved in the course of development of the Wallasey sea front for a Public Aquarium, and in the event of these being successful the Committee trust that they will have the hearty support of members in the always arduous task of collecting funds for the establishment and equipment of the Institution."

MESSRS. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, have just sent out Catalogue, New Series, No. 20, of recent purchases by them of books on zoology, botany, and the physical and mathematical sciences. Upwards of a thousand books and serials are listed.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: An executive secretary to the Library Association—The Hon. Secretary, Library Association, Public Library, Buckingham Palace Road, S.W.1. (Jan. 12). An established analytical chemist in the scientific research and experimental department of the Admiralty at the Royal Naval Cordite Factory, Holton Heath—The Secretary to the Admiralty (C.E. Branch), Whitehall, S.W.1 (Jan. 16). A mycologist in the agricultural department of the Government of Burma—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S.W.1 (Jan. 21). Two chemists in the agricultural department of Nigeria, primarily for work on vegetable oils and nuts, *e.g.* palm nuts, ground nuts, shea nuts, etc.—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, S.W.1 (Jan. 31). A pathologist (morbid anatomy and hæmatology only) at the Royal Prince Alfred Hospital, Sydney, Australia—Hospital Agents, c/o J. W. Vickers and Co., Ltd., 24 Austin Friars, E.C.2 (Feb. 1). A professor of public health at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, South Kensington, S.W.7 (Feb. 16). A reader in chemistry at Bedford College for Women—The Academic Registrar, University of London, South Kensington, S.W.7 (Feb. 17). Civilian education officers in the Educational Service of the Royal Air Force—The Secretary, Air Ministry, Adastral House, Kingsway, W.C.2. A live stock officer for the department of agriculture, Kenya Colony—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, S.W.1.

Our Astronomical Column.

COMETS.—Skjellerup's comet passed perihelion on Dec. 18 and is now rapidly receding from sun and earth; as it remains close to the sun in the sky, its further observation will be very difficult.

Encke's comet should be visible with moderate instruments in January and February. The following ephemeris for 0h is from the *B.A.A. Handbook*:

	R.A.	Decl.	log *r*.	log Δ.
Jan. 10.	22^h $46{\cdot}4^m$	N. 3° 51′	9·987	0·023
18.	22 51·2	3 45	9·920	9·997
26.	22 54·7	3 16	9·837	9·958
Feb. 3.	22 52·6	N. 1 38	9·731	9·903
11.	22 34·6	S. 3 16	9·605	9·836

Perihelion is on Feb. 19·7. After Feb. 11 the comet is too near the sun for observation. On its emergence it will be visible only to southern observers.

RECENT DISPLAY OF THE AURORA BOREALIS.—Judging from the character of the Greenwich magnetograph traces, reports given in the press of the appearance of the aurora borealis on Dec. 26 and 27 are without foundation. Mr. C. Leaf, observing at Cambridge, states, however, that on Dec. 28 "a short-lived but well-marked display was observed here to-night. At 19^h 30^m G.M.T. the sky was clear, but at 20^h 00^m a bright oblong glow was visible low down in the north. Its colour was pale primrose and dark sky was visible below it, except at its western end, where a pale white band reached down to the horizon in the north-west. By 20^h 05^m the glow in the north had entirely vanished, and only a few faint and fluctuating bands in the north-west lasted till 20^h 15^m, after which time the sky was entirely clear."

Mr. Leaf's observations are confirmed in an interesting manner by the Greenwich declination traces. On the evening of Dec. 28, after several undisturbed days, a sharp wave occurred in declination, commencing at 19^h 55^m, reaching a maximum displacement of 21′ eastwards by 20^h 12^m, returning nearly to normal by 21^h 30^m with slight agitation continuing until 4^h on Dec. 29. At the time of the aurora, a stream of spots was about 20° west of the sun's central meridian. These spots reached a considerable but brief maximum on Dec. 28. The coincidence between the occurrence of aurora, magnetic disturbance, and sunspots is noted, but a connexion between these solar and terrestrial phenomena is not necessarily implied in this instance.

Research Items.

AN ANCESTRAL FIGURE FROM NEW IRELAND.—In *Man* for December, Mr. H. J. Braunholtz illustrates a carved wooden figure from New Ireland recently acquired by the British Museum, which belongs to a class of object sufficiently familiar from museum specimens, but of which the meaning and use are still to some extent obscure. The interest of the present specimen lies in the fact that between its legs is an object which clearly represents a friction gong, the *livika* peculiar to New Ireland. This makes the figure unique, although other representations of musicians are known, *e.g.* one playing the pan pipes in the British Museum, and two playing the conch shell and the pan pipes respectively illustrated by Kramer, who describes them as rain-makers. These funerary carvings are only found in the central and northern districts of New Ireland, their region of highest artistic development being the Hamba district, where they have been classified as 'historical' and mythical, the former representing actually known ancestors. One example quoted is that of a famous shark catcher, who was represented with his shark-catching implements. It would therefore be reasonable to regard the present figure as that of a famous *livika* player, though since the *livika* represents a hornbill, it might here represent a totem or might even be a moon-god, of which the hornbill is a symbol. The *livika*, which is manufactured only in a few inland villages, is played at ancestral ceremonies, its sound representing the voice of the spirits. Like the bullroarer, it is then intended to frighten away the women.

CEREMONIAL RUNNERS OF THE FOX INDIANS.—"Contributions to Fox Ethnology," by Mr. Truman Michelson (*Bull. 85*, Bureau of American Ethnology), contains, among other matters, a native text with translation which gives an account of the ceremonial runners of the Fox Indians. The ceremonial runners who, according to this account, ceased to exist about sixty years ago, were three in number, one being drawn from each of three of the four important Fox gentes, the Bear, the War Chiefs, and the Eagle Gens. The member of the Bear Gens was the leader. These runners were blessed by the spirits,—the wind, the deer, and the humming bird. Their functions were carrying messages, especially the news of deaths, and summoning councils; but in addition they exercised a kind of supervision at ceremonial dances, in the councils in case of a division of opinion they gave the decision, and they were rain-makers, or weather controllers. In case of excessive cold they rolled in the snow. To become a ceremonial runner necessitated a severe fast, at the end of which the entrant was blessed by the spirits mentioned above. A detailed account of the instruction given by each of the three spirits is given, in which it is enjoined upon the runner that he shall do his duty cheerfully, shall keep his body clean by frequent bathing, and shall speak no ill of anyone, or mock women. While performing his duty he was to eat no meat but that of the turtle-dove and quail (though at other times ordinary food might be taken), and carry nothing red when sent on an errand to announce a death. His moccasins were to be of buffalo hide, and his offerings to the spirits of tobacco only. Each runner had to make a wooden bowl and spoon, he had to live on the south side of the camp or settlement, and had for his rug the hide of a spotted deer, which it was one of his first duties to obtain for himself by killing the deer. The runners did not marry, and might not be seen by women after childbirth or when otherwise ceremonially unclean, as, for example, during menstruation.

TOXIC EFFECTS OF ROAD TAR EXTRACTS ON TROUT.—In a recent paper, Mr. A. C. Gardiner deals with "The Effect of Aqueous Extracts of Tar on Developing Trout Ova and on Alevins" (*Fishery Investigations*, Series 1, vol. 3, No. 2, 1927. London: H.M. Stationery Office, 1927). The extracts used contained 1·6 parts per 100,000 of 'acid' substances (phenols, etc.), and 0·25 to 1 part of basic substances (pyridine, etc.). It was found in general that susceptibility rapidly increased with age. The fertilisation reaction was unaffected in the tar extracts; and an hour's immersion in these extracts had little or no effect on the subsequent development of freshly fertilised eggs or on embryos 30 days old. Alevins 2 to 3 days after hatching likewise were not harmed by 20 hours' immersion in tar extracts, though they were restless and apparently irritated by the solution. However, from this stage onwards the fry became more and more sensitive, until when 84 days old, none was able to withstand 2 hours' immersion; yearling trout losing equilibrium in 3¼ minutes. There is thus a remarkable increase in sensitivity to tar products as the adult stage is approached, the fertilisation process and the young larvæ being unaffected. These conclusions accord with previous work, and it is pointed out that the lethal action of the phenols on the adult trout is probably due to its action on the gills in preventing normal respiration. No explanation is at present suggested for the relative immunity of the alevins. One might perhaps suggest that the critical factor was the ratio of the amount of respiration through the gills to that through the skin. If the gills were unable to function, the adult would be unable to maintain its normal respiration, and death would occur from suffocation. On the other hand, in the larva, derangement of the gills would probably still allow sufficient respiration to occur through the skin; the large ratio of surface to volume of tissue allowing considerable gaseous exchange. The probability of this explanation is enhanced by the fact that sensitivity to tar extracts increases with great rapidity after about the eightieth day. This would be about the time of scale formation, a process which would rapidly reduce the permeability of the skin to dissolved gases.

TOBACCO AMBLYOPIA.—In the recently published issue of the *Annals of Eugenics*, Miss Elderton has made an elaborate statistical investigation of the data collected by Mr. Usher relating to the incidence of tobacco amblyopia, and has arrived at the interesting conclusion, comforting to many laboratory workers, that excessive smoking in itself cannot be proved to cause tobacco amblyopia. The evidence suggests that if there be a tendency to the development of this visual defect, heavier smoking may hasten the time of onset.

NORTH AMERICAN TERRESTRIAL ISOPODS.—H. Lomander (*Proc. U.S. Nat. Mus.*, vol. 72, art. 17, 1927) has examined the North American Trichoniscidæ in the collections of the U.S. National Museum. He finds three species which are also more or less widespread in Europe—*Trichoniscus pusillus*, *T. pygmæus*, and *Haplophthalmus danicus*, and two non-European species—*T. papillicornis* and *Brackenridgia cavernarum*. It is reasonably certain that *T. pygmæus* and *H. danicus*, which in Europe are generally found in hot-houses and gardens, have been transported to North America from Europe with garden produce, etc. *T. pusillus*, which occurs over the whole of central and northern Europe and is the most common of the terrestrial isopods in the Scandinavian countries, may also be indigenous in the eastern parts of North America. *T. papillicornis*, hitherto found only in the extreme northern portion of the Pacific—Bering Island and Cook Inlet—has, on close examination, been found not to be a Trichoniscus. It belongs to the family Scyphacidæ and is nearly allied to certain species of terrestrial isopods which have been hitherto found only in the Antarctic. This species is made the type of a new genus, Detonella.

AIR BLADDER OF FISHES.—Miss F. M. Ballantyne (*Trans. R. Soc. Edin.*, vol. 55, pp. 371-394; 1927), in an important paper, reviews the present state of knowledge of the evolutionary history of the air bladder of fishes, and extends it by observations on this organ in a number of the more primitive types of living fishes such as Amia, Lepidosteus, Acipenser, Gymnarchus, Ceratodus, and Callichthys. As a result of her work, the author supports the view of Sagemehl, as extended and supplemented by Graham Kerr, that the air bladder of the modern fish is derived from bilaterally symmetrical ventrally placed paired lungs. The author traces the following series of evolutionary stages. First there is the gradual reduction of the left and the enlargement of the right lung, as seen in the young of Polypterus and the adult of Ceratodus. The next stage is illustrated by Amia with its pulmonoid air bladder, which has the normal pulmonary nerve and blood supply, but opens dorsally into the alimentary canal. Lepidosteus has a pulmonoid air bladder with pulmonary nerves but blood coming from the aorta. Acipenser shows a condition in which the reduction of the respiratory function is complete and the air bladder is a simple membranous sac with its blood supply from the dorsal aorta. In Salmo the hydrostatic function has developed further and the air bladder has now red-glands in its anterior walls, but it is still a simple sac opening dorsally into the alimentary canal. The stages from the simple air bladder of Salmo to the complex organ present in the Physoclistic fishes have been worked out by Tracy.

FRESHWATER FOSSIL MOLLUSCA FROM THE ARGENTINE.—From the Pehuenchian beds of the Rio Negro, by some considered as of Eocene and by others as of Senonian age, a small collection of fresh-water mollusca is described by M. Doello-Jurado (*Bol. Acad. Nac. Cien. Cordoba*, vol. 30). The present is stated to be a preliminary notice and deals with only nine species belonging to the genera Corbicula, Diplodon, Physa, Viviparus, and Melania. Judging from the photographic figures, which are very clear, the specimens were by no means in a good state of preservation. It should be noted that they were found in association with Dinosaurian remains.

THE AGE OF THE OCEANS.—In an article entitled "The Problem of Geological Time," in *Scientia* for December, Prof. A. Holmes offers some criticisms of the calculation of the age of the oceans based on their sodium content. This argument, depending on statistical measurements in various parts of the world of the sodium in the ocean and the annual increment by rivers, and corrected by taking into account certain other factors, gave about ninety million years. This figure is far below the estimate based on radioactive minerals. Prof. Holmes believes that the discrepancy lies in a false estimate of the annual sodium increment. The above calculation of J. Joly assumes that 1·9 per cent. of all material added annually to the ocean is sodium, which means, since 10 per cent. of that material is derived from the gases of the atmosphere, that 2·1 per cent. of eroded material is sodium. But the sodium percentage of rocks has been calculated to be 2·85 per cent. for igneous and 0·81 per cent. for sedimentary rocks, giving an average of only 1·32 per cent. Prof. Holmes believes that the analyses of river waters for sodium invariably give too high results, and he thinks that this is because much of the salt in rivers comes from sediments and ground waters and is not new sodium added to the oceans by erosion of the rocks. He denies that the sodium method can give any serious contribution to the problem of the age of the oceans.

WATER SUPPLY OF THE NILE.—In continuation of the study of the regime of the Nile, the Egyptian Ministry of Public Works sent an expedition to the Lake Plateau in 1926. Under the title of "The Lake Plateau Basin of the Nile," Dr. H. E. Hurst has published an account of his work on that expedition (Cairo: Government Press, 1927). The discharge of the Victoria Nile was measured with difficulty, but appears to be about 760 cubic metres per second. The only important inflow to Lake Victoria is the Kagera River, which proves to have a considerably lower discharge than was previously supposed. It was thought to vary between 140 and 1500 cubic metres per second, but Dr. Hurst puts the average flow at not more than 250 cubic metres, and reduces the Kagera's contribution to the lake by about twenty-five per cent. Many more measurements are required throughout the year before the contribution of this area to the water supply of the Nile can be stated with certainty, but so far as can be judged at present, it is not large.

THE PETROLOGY OF THE PACIFIC.—A long paper which summarises all existing knowledge of the mineral and chemical constitution of the volcanic islands of the Central Pacific has just been published by Prof. A. Lacroix (*Mém. de l'Acad. des Sciences*, Paris, 59, 1927). A great many new analyses are presented, and a careful comparison is made with the rocks of the Hawaiian Islands and those of the islands off the South American coast. Throughout the region studied basaltic rocks (including the *andésites* β of Lacroix) with trachytic and ultrabasic differentiates are the dominant types. No granites, crystalline schists, or ancient sediments have been recorded in any form. Three main series are distinguished according to the marked or virtual presence or absence of nepheline and its equivalents. In a few localities dacites and rhyolites are present, but the typical 'andesites' of the circum-Pacific facies (*e.g.* hypersthene-andesites and *andésites* α of Lacroix) are wholly absent. Prof. Lacroix is characteristically cautious in drawing conclusions about the nature and structure of the sub-Pacific crust, and as to the meaning of the regional variations, he remarks: "Il faut reconnaître que les causes du phénomène nous échappent pour l'instant."

GRAVITY SURVEY BY SUBMARINE.—Investigations in gravity observations during the voyage of a Dutch submarine from Holland to Java via the Panama Canal in 1926 were the subject of a paper read by Dr. V. Meinesz on Dec. 12 to the Royal Geographical Society. The apparatus, consisting of three practically isochronous pendulums, was described in detail. It proved satisfactory and the influence of the ship's movements were effectively eliminated. Only provisional figures can be given, but Dr. Meinesz believes that the error arising from the ship's movement is only 0·0008 cm. in g. There are, however, other sources of probable error, including a very small error due to the uncertainty of the chronometer rate, and others which are very difficult to determine, caused by the velocity of the ship and the speed of currents. Only preliminary results are available, until the computation of the observations by the United States Coast and Geodetic Survey are completed. One of the most interesting discoveries is the occurrence of positive anomalies in both Atlantic and Pacific Oceans. After isostatic reduction, the mean of 17 purely oceanic stations in the Atlantic gave an anomaly of +0·025 cm. and the mean of 14 similar stations in the Pacific +0·020 cm. These anomalies do not correspond to a pure longitude term and are greater than those that might be expected because of the deviation between the geoid and the spheroid caused by a corresponding distribution of mass. Several other preliminary results were also discussed in the lecture, which is to be published in the *Geographical Journal* (*v.* also NATURE, Dec. 17, p. 898).

THE HALL EFFECT IN IRON CRYSTALS.—The July issue of the *Proceedings of the Cambridge Philosophical Society* contains a paper by Dr. W. L. Webster on the Hall effect in single crystals of iron. The plates used were cut parallel to one or other of the faces of the crystal, were about 1·3 cm. long, 0·7 cm. broad, and 0·016 cm. thick, and were tested in magnetic fields up to 22,000 gauss. The Hall effect was balanced by means of a potentiometer. Up to 21,000 gauss the effect is proportional to the field and after that remains constant. Its value is identical for the specimens used and for pure iron, and there appears to be no connexion between the effect and the change of resistance of iron crystals in a magnetic field.

HARDNESS AND TEMPERATURE.—The results of Mr. E. G. Herbert's investigation of the effect of temperature on the hardness of metals, were communicated to the Institution of Mechanical Engineers at the meeting on Dec. 2. The hardness is tested by a pendulum hardness tester provided with a spherical faced diamond of 0·5 mm. radius, which rests on a short block of the material to be tested of 13 mm. square section kept at the desired temperature by an electric furnace. Where the specimen is of steel, it is heated to a temperature between 900° and 1300° C., quenched in water or oil, and tested either immediately or after a further heating to 400°-700° C. and slow cooling. High speed steel after the first heating and quenching has a hardness which decreases slowly with rise of the temperature of the test to 600° C. and more rapidly at higher temperatures. The further heat treatment decreases the hardness at low temperatures but raises it at high temperatures, so that it is nearly constant up to 600° C. As the materials cut by the tool steel are hardened by the operation, tests of this hardening have been made and it is found to be closely related to the ductility of the material.

MODIFICATIONS OF CANE SUGAR.—In the *Chemiker-Zeitung* of Nov. 12, Prof. von Lippmann gives a brief account of some investigations which were begun in Japan by Dr. Helderman and are being continued at Utrecht by Prof. Ernst Cohen, on the existence of modifications of cane sugar. In the special number of the *Zeitschrift für phys. Chemie* dedicated to Prof. Cohen, Helderman describes two distinct modifications, precipitated by methyl and ethyl alcohol respectively from aqueous solutions, of which the latter is the more stable at ordinary temperatures. Since the specific gravities and heats of solution show considerable differences, it is obvious that all physical constants of cane sugar will have to be re-investigated.

CONSTITUTION OF COLLOIDAL PLATINUM.—In the *Journal of the Chemical Society* for October, S. W. Pennycuick gives an account of an investigation of the constitution of colloidal platinum. Platinum sols do not require the addition of stabilisers, and so it was possible to prepare sols by sparking pure platinum electrodes in pure conductivity water, great care being taken to exclude all impurities, including carbon dioxide. The conductivity of such a sol at 25° increased over a period of several days, and approaching a limiting value. This equilibrium could be quickly reached by boiling for a few minutes. After any temperature change, however, there was a lag in the equilibrium as indicated by conductivity measurements. Sols with conductivities of more than 40 gemmhos at 25° were prepared. Pennycuick supports Pauli's theory, according to which some of the platinum is oxidised on disintegration, and in contact with water acts as an electrolyte, probably H_4PtO_4. This acid gives rise to the formation of complex anions which are in equilibrium with free hydrogen ions. Experiments on the titration of platinum sols with alkalis confirm the presence of free hydrogen ions, and it suggested that in addition to these, there is a surface layer of hydrogen ions on the complex anion. A change of temperature causes a measurably slow rearrangement of the equilibrium. The titration curves show that the sols are not strictly comparable with either strong or weak acids.

DEVIATION OF WIRELESS WAVES AT A COASTAL BOUNDARY.—Major J. P. G. Worlledge, writing from the United Service Club, Pall Mall, London, S.W.1, refers to the reflection of wireless waves suggested by Dr. A. H. Davis and Dr. R. L. Smith-Rose in a communication by the latter to NATURE of Sept. 19, 1925, p. 498. In the course of some experiments carried out at a direction-finding station during the period January to October 1927, Major Worlledge has obtained evidence of the reflection of wireless waves at a coast line. During the calibration of the direction-finding station it was noted that the bearings on certain stations, using more than one wave-length, showed abnormal variations accompanied by sudden shifts of as much as four or five degrees on wave-lengths in the neighbourhood of 1000 metres. As a result of systematic observation, it was found that the change in bearing was related in a harmonic manner to the frequency of the waves received. The period of this harmonic relation was found to be consistent with the explanation that the change in bearings was due to the reflection of waves from the landward side of the neighbouring coastline. In such circumstances two waves would be received, the direct and reflected waves, and the error in apparent bearing would depend upon the path difference of these waves in terms of the wave-length employed. The maximum deviations of bearings are observed when the wave-length is such that the direct and reflected waves arrive in the same phase, while at intermediate wave-lengths, blurred minima are observed on the direction-finder as a result of the difference in phase of the two waves. In most practical cases the matter is complicated by the fact that reflection may take place from more than one point on the coast-line, and Major Worlledge has arrived at the above explanation only by subjecting a large number of observations to periodogram analysis and comparing the results with accurate maps of the neighbourhood. The theory of the subject has been developed concurrently with the experiments and has given satisfactory agreement.

The Overthrusts of the Trans-Alai and Alai Chains.

By Prof. D. J. Mushketov, Director of the Comité Géologique of the U.S.S.R.

The great plains which run south-eastward from the Sea of Aral contract to the basin of Ferghana, which lies between the great crescentic curve of the Thian Shan to the north, and a series of chains which abut against the Pamir and the mountainous northern projection of Western India. It was shown by J. V. Mushketov, by surveys between the years 1874 and 1880 (described in his "Turkestan," 1886), that in the Alai Mountains the Palæozoic rocks were overturned in many places, and rocks that are not normally in contact had been brought together over wide areas. These facts were not followed up at that time nor by the systematic survey of Turkestan, which began in 1909. That survey showed that in addition to the Palæozoic rocks being overturned northward the Alai chain is traversed by large fault lines with surfaces sloping southward, and that its Kainozoic and Cretaceous deposits show in many places a paradoxical dip under the Palæozoic, and that exotic cap-shaped masses of the Palæozoic rest on younger rocks.

The geological survey of the Ura-Tuba region, that is, of the northern slope of the Turkestan chain between the valleys of Lialliak and Zaamin Rivers, which I began in 1925, added much to the information regarding the eastern Ferghana: and the study of the numerous northerly curving Palæozoic band-shaped horsts prove the predominance of pressure from the south during the Kainozoic orogenetic processes. These preliminary observations were verified and completed in 1926 by my collaborator, A. P. Markowski, and later in 1927 by myself from the clear sections along the Lialliak River.

The fundamental element of the tectonic structure in this area appears to be an inclination towards the north of long band-shaped Palæozoic blocks which trend west and east and are uplifted at the southern end and plunge downward at the northern end.

The formation of some oblong depressions (Rhabat, Bujun, and others) and many morphological peculiarities of the region appear to result from the mechanism which produced this widespread basin structure.

The second series of interesting observations were made during the past summer (1927) in the second part of my journey across the intersection of the Trans-Alai chain, along the Altyn-Dara River, and along the northern slope of the chain from the summit Khtai-Saz to Mt. Kaufmann, 26,000 ft. high.

The western part of the Trans-Alai chain is more complicated and interesting than the eastern part, and fully confirms the already known discordance between the structure of the eastern, or rather the middle part—the Kyzylart, and that of the Peter the Great Mountains.

These observations lead me to the following conception of the structure of the northern slope of this part of the Trans-Alai chain. It is a large isosyncline (about 3 km. wide) which is highly overturned to the north, and is lying almost horizontal; it consists largely of Lower Mesozoic red flaggy sandstones, which rest discordantly upon a base that consists of Upper Silurian limestones and that rises slightly above the floor of the valley. The core of this syncline is highly crumpled and includes 16 to 20 steep fan-shaped folds of Upper Cretaceous and Eocene marls and clays; they are raised by this folding to a height of 18,000 ft. in Mt. Khtai-Saz and other peaks. The southern limb of the syncline is truncated by the overriding from the south of the Lower Cretaceous red series, which, in their turn, are overridden by the Palæozoic beds containing effusive rocks that form the southern slope of the Trans-Alai chain.

Probably, moreover, the whole mass of the Trans-Alai chain, together with its Palæozoic base, was overthrust on to the Alai chain, thus occasioning the southward slope of the Alai chain while a large longitudinal displacement began the formation of the Alai valley. The morphological evidence of this fact, announced in 1903 by the American geologist Pumpelly, is now supported by direct geological proof, by the inclination and disappearance under the Alai valley of the Cretaceous and Kainozoic series of its northern bank (Daraut, Gaz, Sake-Yar). There, of special interest, is the sharp turn of the syncline from an east to west into a meridional strike, accompanied by an overturn to the north; for this change in direction is a supplementary proof of the influence of the southern or Pamir (Alpine) pressure. This change in direction takes place east of the meridian of Mt. Kaufmann, in accordance with the beginning of the curvature of the whole Alai chain into the 'Ferghana flexure.'

Observations on the southern limb of the flexure, between the Alai valley—along the Taldyk River, the southern Yagatch-art and the valleys of Katta-Karakol, Ak-bosagha and Archat—prove the occurrence (along an extent of about 100 km., from the mouth of the Kara-Kavak River, and extending up the southern slope of the Alai to its crest, and farther, beyond Yagatch-art, down the northern slope of the chain) of a large overthrust sheet of the massive Lower and Middle Devonian limestones. This sheet has been followed from south to north, and these limestones are in an absolutely abnormal position, as they lie above the Kainozoic and Cretaceous series and are in apparent accordance with them.

The width of the overriding and the thickness of the masses intersected by it diminish from west to east, in such a manner that on the west the younger series are generally squeezed out and are absent; and then gradually along the overridden band appear younger and younger series, first Cretaceous and finally Tertiary. Thus, to the east of Ak-bosagha, the Devonian deposits lie beneath red sandstones and conglomerates that are very high in the Kainozoic. The surface of the overriding sheet dips distinctly 35° S.E.

The observations of the past season complete the previous data and entirely confirm the conclusions which I have expressed at different times, particularly as to the 'Pamir orogenesis,' and also my preliminary diagrammatic section from the Pamirs through the Alai up to Ferghana (Izvestia Comité Géologique, 1926, No. 1).

The important observations of the recent Pamir expedition of the Comité Géologique of the U.S.S.R. under the leadership of Prof. D. V. Nalivkin are entirely in agreement with those previously mentioned. Prof. Nalivkin has conclusively proved the arch-shaped bending to the north of all the tectonic elements of the Pamir described by myself in 1917, and that the structure consists exclusively of Mesozoic and Tertiary series with Palæozoic rocks overriding them to the west of Kyzylarchat; he has discovered marine Jurassic deposits at the base of a Mesozoic complex along the Markansu valley, and has shown the analogy of the Jurassic formations of the Pamir with those of Western Bukhara; he has also proved the presence of Mesozoic rocks in the region of Mus-Kol; and, finally, he has confirmed the general overriding of the whole Pamir system northward.

Water Powers of Canada.[1]

UNDER the above heading, the Canadian Department of the Interior has just issued a brochure of 94 pages replete with up-to-date information respecting what is perhaps the most striking of all the natural resources of the great northern Dominion. In a foreword, the Deputy Minister, Mr. W. W. Cory, says: "In the vast domain of Canada, the countless rivers and streams, flowing with never failing replenishment from upland to sea, provide to the people of the Dominion an extraordinarily valuable and widely distributed asset in water-power resources which, already, has contributed in great measure to industrial progress, and which assures a supply of low-cost energy sufficient to meet expanding requirements for many years to come." To this may be added from the report itself: "It is not too much to say that, apart from the human factor, water-power is the most vital force behind Canadian industrial development."

As the subject of water-power development in Canada was dealt with by Dr. Brysson Cunningham in two articles which appeared in NATURE on Aug. 27 and Sept. 3 last, it is not necessary to recapitulate such information as is therein contained, but, the present report being of later date, there are several supplementary details of interest to which attention may be directed. The total turbine installation has now (Nov. 1, 1927) been increased to 4,883,266 horse-power, of which 4,012,428 horse-power is in connexion with central electric stations and 526,731 horse-power in connexion with pulp and paper mills, leaving a residue of 344,107 horse-power distributed over a miscellaneous group of industries, ranging from electro-chemical plants of considerable size to the lowly grinding mill serving local needs with a 5-horse-power wheel. The average of ·513 horse-power per thousand of the population places Canada second to Norway in *per capita* development, while in aggregate installation she ranks second to the United States. The capital invested in the water-power industry in Canada is estimated at nine hundred million dollars, or more than that invested in any other single manufacturing industry. The corresponding figure in 1910 was 121,000,000 dollars, so that the increase in seventeen years has been more than six hundred per cent.

The outstanding significance of the location of the Canadian water powers is their favourable distribution for development purposes. Eighty-two per cent. of the developed water-power and roughly sixty per cent. of the total resources are situated in the coal-less provinces of Ontario and Quebec, where more than eighty per cent. of the manufacturing industry of the Dominion is carried on. It is this propitious circumstance which has not only enabled Canada to compete successfully with mass production in other countries, but has rendered her industrial structure largely independent of foreign fuel. Moreover, it is attracting to the Dominion important industries from abroad. Already 1400 branches of United States factories are stated to have been established in Canada. In certain specialised products the raw material from other countries is being imported for treatment by low-cost water-power. The bearing of this economic factor on the future welfare and progress of the Dominion can scarcely, as yet, be adequately estimated, but it is bound to be of great importance.

The brochure not only contains a wealth of figures and statistics, detailing the development in each of the provinces of the Dominion, but also it is illustrated by maps, diagrams, and a number of interesting photographs.

---

The Relation between Rainfall and Flow-off.

IN Great Britain, knowledge of rainfall distribution is relatively detailed and exact. Moreover, most of the rainfall measurements which have been made are available to all who desire to consult them. On the other hand, the information which has been published regarding the flow-off of rivers is, by comparison, very slight in amount and most incomplete. A fair amount of data regarding flow-off has been spasmodically collected by various parties who are interested in the yield of certain rivers from the point of view of water-supply, but for reasons which are not connected with the increase of scientific knowledge, such data generally remain unpublished and inaccessible to the general student of the economy of rivers.

In some other countries the case is quite otherwise. Thus, the data published about the run-off of the more important rivers of the United States of America is very considerable, and would easily bear comparison with the corresponding rainfall data available for that country.

As a result of the conditions prevailing in Great Britain, there has grown up a devious method of obtaining an estimate of the average annual flow-off of a river. This method starts with an average annual rainfall map of the area drained by the river, and proceeds to make allowances for losses by evaporation, percolation into other river-basins, etc., and so arrives at an estimate of the average annual yield of the stream. As a rule, next to nothing is known about the magnitude of the losses, and in practice a quantity equivalent to from 10 to 14 inches of rainfall over the area is assumed to represent them. It needs but little consideration to appreciate the fact that measurements of evaporation from water-tanks and of percolation, as usually made, are carried out under conditions which bear but little resemblance to the corresponding conditions in the drainage area, and that they, therefore, find no direct application to the problem.

When a local authority produces a scheme for the appropriation of the water of a stream for purposes of water supply, it is of course incumbent on the authority to obtain parliamentary sanction for the adoption of the scheme. It is interesting to note that, in the records of the proceedings of the parliamentary committees which are appointed to hear evidence for and against such schemes, it is common to find considerable argument developed around the value to be assigned to the average annual rainfall over the catchment area, even if the various estimates of the value do not markedly differ among themselves; whereas the empirical figures which are deducted on account of losses by evaporation, etc., are often accepted without question. No doubt the reason for this unscientific procedure is that rainfall data are numerous, and there is ample scope for argument in reference to the method of applying them to the problem in hand, whereas trustworthy data for evaporation from the area are entirely wanting, so that in the absence of run-off data, no opportunity for argument occurs in respect of the allowance to be made for losses.

The present investigation by Capt. W. N. McClean of the rainfall over the area drained by the River Garry in Inverness-shire and of the run-off of the stream[1] is of considerable interest from this point of view, for it provides the means of comparing the two quantities and so forming an estimate of the losses due to evaporation and percolation in that area. The River Garry is situated in one of the wettest regions of the British Isles, the average annual rainfall being in excess of 90 inches. The investigation is the first of its kind to be made in Great Britain in respect of a stream in an abnormally wet region.

A map of the average annual distribution of rainfall over the area is the basis of the rainfall side of the work. A method is then developed whereby the total quantity of rain which falls over the area in any day can be estimated from measurements made at a few gauges in the valley. It is very difficult to assess the accuracy of these estimates. No doubt the error may be considerable on an individual day, but over a period of about a month the aggregate error should be much less.

The estimates of run-off of the stream were made by means of a continuous record of water level, combined with measurements of velocity at various points in the cross-section of the stream, and on various occasions. A calibration table is thus drawn up which enables values of water-level to be immediately converted into values representing the discharge of the stream.

In comparing rainfall with run-off due allowance is made for the storage in the river basin.

A balance-sheet of rainfall and flow-off is prepared by dividing the observation period of the three years 1913 to 1915 into parts each about a month in length, beginning and ending at times when rainfall was slight and the water in transit had fallen to a minimum. The net loss of each period is thus determined. These losses are presumed to be accounted for by evaporation, percolation, and (in winter) by storage in the form of snow. In spring, and sometimes in winter, the balance-sheet may show net gains: these are ascribed to the effects of melted snow which had previously been stored. The average loss is about 8¼ inches (of rain) per annum. The figure is a low one in comparison with the values usually accepted. It could readily be increased by supposing that the rainfall has been underestimated, and for such a supposition there is some ground.

The three years included the year 1915, which had an abnormally dry summer in the North of Scotland. From this circumstance the author is able to compile a valuable table of estimated lowest possible flow-off. This table depends only on the measurement of flow-off. The table in turn provides the necessary data for the computation of the maximum storage required to provide a continuous rate of draw-off.

The paper is a valuable contribution to our knowledge of the economy of a river situated in a region where the rainfall is very large.

R. CORLESS.

Anthropometric Measurements and School Progress.

A PAPER entitled "Body Measurements, Respiratory Tests and School Progress," which has an important bearing upon the methods and uses of anthropometric measurements of school children, was read before the Royal Anthropological Institute on Dec. 20, by Dr. A. A. Mumford, Medical Officer of the Manchester Grammar School. Body measurements have been taken annually at the Manchester Grammar School by the inspector of physical training on a uniform system since 1881. These measurements have been used to test growth and stimulate the use of the gymnasium by individuals below normal. Since 1909 the School Medical Officer has used these measurements to assist him in forming judgments about the satisfactoriness or otherwise of the boys' growth. With the co-operation of form masters it has been possible to correlate them with the boys' school work and conduct, and the records of each individual have been kept on cards which show the whole of the boys' school career at a glance.

By adapting a method suggested in a paper published in NATURE by Mr. Cecil Hawkins, height, weight, and chest girth were arranged and graded in half-yearly age groups in 5 per cent. percentiles. These groups made it possible to distinguish tall and small, thin and stout, narrow- and broad-chested, and also indicated in which one boy surpassed or was behind another.

It became apparent that it was desirable to carry out tests of functional as well as structural peculiarities, and respiratory tests were added. The tables were then graded on a time increment basis, which showed advances on the average in units of six months. The metric system of measurements was adopted, making it possible to use measurements of height and chest girth for calculations of volume, the true specific gravity being obtained in the swimming bath. Measurements were also made of particular parts of the chest. It was thus possible to advise parents and masters as to the kind of activity which would appeal most strongly to the boy or of which he stood in most need.

The observations showed that there was no single or uniform ideal boy, but that there were natural and essential differences which had to be found out, studied, and if possible measured. In seeking for a guiding principle to body build and shape in relation to physical activity, much help was obtained from the study of ancient brasses and from scientific tailoring, as well as from the measurements of records for the American Army, from which it was realised that there are special forms of body build which stand in relation to special forms of bodily exercise, and that each form of exercise makes special demands on body form and requires special methods of respiratory action. Hence the School Medical Officer needs to appreciate how wide are the differences in physical equipment between different individuals in relation to subsequent as well as school life. The basis of these differences is anthropological and must be studied in terms of functioning of the whole body. Sir Arthur Keith in his work on the mechanism of respiration in man, on the posture of man, its evolution and its disorders, and on the evolution of human races in the light of the hormone theory, has contributed greatly to the needs of the School Medical Officer.

Inquiry shows that body measurements and respiratory tests are also related to mental activity, and of the capacity to withstand and to recover from the mental strain in school life. The measurements of the School Medical Officer should be compared with the reports of the boys' progress furnished by the masters. Without such periodic reviews it is impossible to judge the effect of mental concentration on the boy's present growth or future fitness. Observation has shown that although undue absorption in either mental or physical activity involves damage, proper exercise of physical powers is probably very beneficial to the cultivation of mental powers. An inspection of figures relating to boys who have gained entrance scholarships to Oxford or Cambridge during the past twenty years points in a similar direction. It was evident that boys winning scholarships at Oxford and Cambridge tended to display a somewhat accelerated physical growth when compared with the average boy. They also possessed a slightly better physical frame. This was most marked in boys winning first-class honours, and indicated that these boys maintained their position with less strain owing to a combination of higher mental ability and a superior bodily physique. In the boys of the next two grades the acceleration was less marked, indicating the strain of a lesser mental and physical ability. On the whole, the honours group excels in sports as well as brain.

The study of the adaptability of the human frame to meet the demands of energy involved by the various forms of mental and bodily work required in modern civilisation should be one of the principal objects of the modern School Medical Officer.

University and Educational Intelligence.

Cambridge.—Mr. H. L. H. H. Green, Sidney Sussex College, has been appointed demonstrator in anatomy.

An election to three Beit Fellowships for scientific research will take place on or about July 16. Candidates must be of European descent and graduates of a university of the British Empire or of equivalent standing. The fellowships are of the annual value of £250 and are tenable at the Imperial College of Science and Technology. Forms of applications and all information may be obtained, by letter only, from the Rector, Imperial College, South Kensington, London, S.W. Applications must be received on or before April 20.

Two Theresa Seessel research fellowships, each of the value of £300, are being offered by Yale University for the promotion of original research in biological studies. Preference will be given to candidates who have already obtained their doctorate, and demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications, accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate, should be made to the Dean of the Graduate School, New Haven, Conn., U.S.A., before Mar. 1 next.

We have mentioned before in these columns "Poverty Problem" lectures of the University of Calcutta. The lecturer, Captain J. W. Petavel, has epitomised them in a volume entitled "The Plan of the Educational Colonies Associations." These associations have been formed, one in India and the other in England (Hon. Sec., J. B. Pennington, 3 Victoria St., Westminster, S.W.), to encourage pioneer efforts to put the plan into operation. Teachers in the proposed colonies are to be paid only on a half-time basis, as most of their time will be spent in running their own small farms or workshops with the help of groups of pupils. The scheme has received influential support in Calcutta. In the June number of *School Life*, the organ of the United States Bureau of Education, there appeared an account of the Educational farm colony of Rabun Gap, Georgia. This colony is based, in the main, on the principles on which Captain Petavel relies; that is to say, each family resides on its farm, the labour of the children is largely utilised, under skilled direction, in conducting the necessary farm operations, the produce furnishes nearly everything that is eaten in the colony, and a market is thus created for the farmers. The whole plant is utilised for educational purposes, and especially to make better farmers and citizens.

A distinguishing feature of the Rabun Gap colony is its system of 'rotating farm homes.' Each of the 20 families accommodated on the colony's 1500 acres is admitted for a period of five years only, and this is liable to be curtailed if the family does not 'make good.' At the end of its tenure it is expected to have attained to high standards of farm practice and of living, and to carry these with it elsewhere; its children meanwhile having had a good grounding in the ordinary school subjects and a training that should enable them eventually to become successful owners or managers. The scheme has been in successful operation on a self-supporting basis for twenty years. A contributory cause of its success is that the families are chosen from among more or less isolated hill crofters accustomed to a meagre and rough life. Whether it would have succeeded with people of the type of those from among whom Captain Petavel proposes to recruit his colonists is open to doubt. It is now, owing to a disastrous fire, to be re-established as a public utility corporation associated with the local education authorities. Half a million dollars are to be spent on the equipment of the reorganised colony.

We have received a new and revised edition of "A List of the Serial Publications available for consultation in the Libraries and Scientific Institutions of the Union of South Africa." The List has been compiled for the Research Grant Board of the Department of Mines and Industries by Mr. A. C. G. Lloyd, the librarian of the South African Public Library, Cape Town, who has had the assistance of Mr. Percy Freer and Miss M. Ralling, members of the staff of the library. Notices of previous issues of this list appeared in Nature in 1912, 1917, and 1921. It is remarkable that the number of serial publications catalogued in the list has more than doubled since 1921, having increased from 1350 to 3117. We must suppose that the greater part of this increase must be ascribed to the energy shown by Mr. Lloyd in collecting the necessary information from the various libraries and institutions scattered throughout South Africa, and we congratulate him on the successful accomplishment of a very difficult piece of work. Some forty-four libraries have been consulted, and these include the fine mathematical library of Sir Thomas Muir, which is destined to form part of the South African Public Library. After the title of each publication an indication is given as to the libraries in which it may be found. In every case all gaps in the sets are carefully noted, so that an opportunity is given for bringing pressure to bear upon librarians who should take steps to complete their sets. English and American serials are entered in their alphabetical order, but foreign publications are entered under their place of publication. We prefer the alphabetical arrangement of all journals as carried out in the "World List of Scientific Periodicals." However, the South African list has an alphabetical index containing the names of most of the foreign periodicals, with references to their position in the body of the work.

Calendar of Customs and Festivals.

January 9.

PLOUGH MONDAY, the first Monday after Epiphany, an ancient popular festival which marks the close of the Christmas and New Year celebrations. It has been explained as the day on which agricultural work is resumed after Christmas, and it is compared with St. Distaff or Rock Day, Jan. 7, the day after Epiphany, when the women are supposed to return to their work. On St. Distaff's Day a contest between men and women took place, the men burning the women's flax and the women drenching the men with water. A similar contest sometimes took place on Plough Monday. If the ploughman could rise sufficiently early in the morning to place his whip, ploughstaff, or other field implement by the fire before the maid put the kettle on it, the maid lost her shrove-tide cock, and vice versa.

Although Plough Monday is said to mark the return to work, the observances recorded have also been described as a festivity of the workers similar to that enjoyed by their masters during the holidays. Superficially they have that appearance rather than of a resumption of labour. Before the Reformation, candles were burnt before some of the images in the church, and a collection was made for the cost of the 'Plough lights'; but this part of the custom did not survive the change, although the levy of money continued to be made.

The essential feature of the custom was that a band of young men, sometimes with their shirts worn over their coats, sometimes in their shirt sleeves, and bedecked with ribbons, drew a plough, also dressed in ribbons, and sometimes called the 'fool plough,' to the principal houses in the neighbourhood, where they expected to be regaled with bread and cheese and ale, or to receive gifts of money. If there were no immediate response, and a tremendous din of shouting and blowing of horns produced no result, the ground in front of the door was ploughed up. The day ended with a merrymaking on the proceeds. The men who drew the plough were known as 'plough bullocks'—in Huntingdonshire as 'plough witchers.' In Lincolnshire the procession included thrashers carrying their flails, reapers with sickles, and all who were in any way connected with the work of the field, even to the smith who sharpened the plough, and the miller. As usual in folk mummings, important personages were 'the Fool' and 'Bessy,' a man dressed in woman's clothes. The latter carried the money box; the former had an inflated bladder, and was dressed in the skin of a calf, or in one case of a fox with dangling tail. Bessy sometimes had an ox-tail dangling beneath his skirts. It is significant that chasing and belabouring with sticks a man dressed in a calf skin was a Hogmanay custom in Scotland.

When brought into relation with customs found elsewhere, the object of the Plough Monday celebration becomes clearer. Certain Rumanian observances will serve. In the ceremony of 'the great plough' (*Plugul Cel Mare*), which takes place on the morning of Jan. 1, a number of young men go around to the houses of the wealthier people. Eight are harnessed to a real plough, one is equipped as a sower who precedes the plough and sows corn in its path, while another carries a friction drum made of wood, goat's skin, and horsehair, with which the lowing of oxen is imitated. On arriving at their objective, two of the party recite a long poem, which describes all the stages of Trajan's harvest from the sowing of the corn and its fertilisation by the rain, to the reaping and carting of the crops, and how Dochia (the daughter of the last king of Dacia conquered by Trajan) makes and bakes cakes for the workers. The verses close by wishing equal good fortune to the inmates of the house.

From these two customs, then, it would appear that the object of drawing the plough about on Plough Monday, a practice which had degenerated into little more than a noisy piece of horseplay with the object of raising contributions towards a merrymaking, at an earlier stage had been to wish or, more properly, to secure good luck and prosperity to those to whom visits were paid. Like other festivals of the kind, it must originally have been communal in character. The circulation among neighbouring houses at first was probably inclusive, a communal rite intended to secure the well-being of the whole society, as is usually the case. Among the Gilyaks, for example, at the slaying of the sacred bear, the animal was taken round to every house in the village.

Such a communal purpose may suggest an explanation of the even more primitive features. The Fool and Bessy, the two characters who appear constantly in folk dances, may usually be taken to represent the male and female principles in Nature, and their presence in the ceremony the promotion of fertility: the Fool in wearing the skin of the calf is identified with the animal itself, which is further indicated by the appellation of 'plough bullocks' given to those who draw the plough.

As a parallel may be cited the wolf dance of the Sioux, in which the dancers identify themselves with the wolf by wearing wolf skins and gather round the one who represents the buffalo to pull him down, thus magically securing the supply of buffalo meat; and the buffalo dance of the Mandans, as recorded by Catlin, in which they wear buffalo skins. The Fool and those who draw the plough may therefore actually be regarded as a survival of the belief in their identity with the oxen, the beating of the cow skin in Scotland possibly being a representation of the killing of the sacrificial animal to promote the strength of the deity which it represents. Sir James Frazer has shown that the corn-spirit is often represented by a bull or other animal which is sacrificed. The high leaps of Bessy, which showed her stockings and breeches, may be compared to the leaping of the dancers of many parts of Europe, by which women in a mimetic dance promote the springing of the corn.

HANSEL MONDAY.—The first Monday in the New Year, or more commonly Old Hansel Monday, on the first Monday after Jan. 12 (*i.e.* Jan. 1, O.S.) in Scotland was celebrated by gifts similar to our Christmas boxes. A liberal entertainment at breakfast was given to the farm-hands, and the rest of the day was a holiday. Servants were also engaged for the year. It was the principal day for making trial and forecasts of the future. In Skye a form of weather divination was practised at this time. It is a common and widespread custom to regard the weather of each of the next twelve months as being foretold by that prevailing on each of the twelve days between Christmas and Epiphany.

In Scotland the twelve days were sometimes reckoned in this period, then known as "the twelve days of Christmas"; by some from New Year's day; but in Skye, the period began with Hansel Monday. In the Balkans "a dry Epiphany and a dripping Eastertide" foretell plenty, and may be compared with "a green Yule makes a fat churchyard." Apart from the weather, the period between Christmas and Epiphany was peculiarly favourable for all forms of popular prognostication.

Societies and Academies.

LONDON.

Optical Society.—Dec. 8.—**T. Y. Baker**: The design of reflecting prisms. In the majority of reflecting prisms used in optical systems, reflections most frequently take place at angles of 45°; and the planes of successive reflections are either the same or perpendicular to one another. The reason seems to be that these systems are easily portrayed on a drawing board. Any angles of incidence and any alterations in the plane of reflexion can be dealt with by the construction of a spherical diagram, either by measurement of an accurately drawn diagram on a sphere, or by computation by spherical trigonometry. From the data derived from the diagram, a wire model of the axial ray in its passage through the prism can be constructed. Next a wooden model of the full beam of light is constructed, and finally a model of the complete prism. Among the systems examined is that used in the prism binocular. Apparently a systematic examination of the possible prisms has never been made, but if it were done a skew prism of compact form and without re-entrant angles which could be made in a single block of glass might be found.

Geological Society, Dec. 14.—**Edward Greenly**: The Lower Carboniferous rocks of the Menaian region of Carnarvonshire: their petrology, succession, and physiography; with palæontological notes by **Stanley Smith**. The term Arvon is a convenient designation for the region. The Lower Carboniferous rocks of Arvon consist in the main of a limestone series with many beds of sandstone and shale. This is underlain by a singular formation, composed of yellow and red loams and breccias, which are studded with pisolites of gothite and kaolinite. The blocks in the breccias are angular, and the loams are unstratified. The loams are of alien, the blocks of local, derivation. The limestones are rich in corals and branchiopoda, and are all in the zone of Dibunophyllum. The structure is that of an asymmetrical synclinal infold, truncated by a large boundary-fault. The series rests with complete unconformity upon the Mona complex and the Ordovician rocks; and there is rapid overlap in a west-north-westerly direction. From the direction of the overlap, and from the contents of the conglomerates, it is inferred that the region which is now Snowdonia was completely submerged in Lower Carboniferous times. At first, the climate seems to have been arid, with a large diurnal range of temperature; but, as the subsidence advanced, moist and genial conditions began to set in, persisting throughout the remainder of the period represented by the limestone series.

Linnean Society, Dec. 15.—**K. Münster Ström**: Recent advances in limnology. The object of limnology as a synthetic science is to investigate the reciprocal action of biotopes and biocoenoses, and the cycle of organic substances within the microcosms represented primarily by the lakes. Recent researches confirm that the three biological lake types, *eutroph*, *oligotroph*, and *dystroph*, recognised by Naumann and Thienemann, must be regarded as natural, and should form the basis of attempts to establish more detailed classification schemes. A scheme embracing all lake types known at present is put forward which is based upon the (N+P), Ca, and humus 'spectra' proposed by Naumann for expressing the position of an individual lake with regard to those essential factors.—**T. A. Stephenson**: On species among the Cœlenterata. Cœlenterate species are difficult to define. The characteristics of the nematocysts have been suggested as useful criteria, for they are characteristic and their variations appear to be arbitrary. The species of British Actiniaria are sharply marked off from one another by their methods of reproduction. The structure of the nematocysts is a useful generic and family character, and their size sometimes distinguishes species; but in critical cases they give no assistance, and differences of habits are the decisive factors.

EDINBURGH.

Royal Society, Dec. 5.—**E. T. Whittaker**: The influence of gravitation on electric phenomena. The address described the attempt of Faraday to find experimentally a connexion between gravitation and electricity, and the discovery by Einstein of the true principle of the connexion. The author has recently completed work on electric phenomena in the field of a single gravitating mass and in a uniform gravitational field.—**C. G. Darwin**: The new outlook on the mechanics of the atom. The address gave an account of the recent developments in the wave theory of matter, with especial reference to the description of motions, as opposed to stationary states.—**N. B. Eales**: The anatomy of a fœtal African elephant, Part 2. The muscles of the trunk and limbs. The dorsal muscles and ligamentum nuchæ are strengthened to carry the weighty head, which is heavier than in and other terrestrial mammal. Occipital muscles are fixed so far back as the thoracic vertebræ, and some of the cervical and thoracic muscles are firmly fixed to the pelvis and sacrum. Both limbs have enhanced extensor and weak flexor muscles. The five digits are prevented from spreading by strong lateral ligaments. In its musculature the elephant shows no close affinity with the Ungulata.—**H. W. Turnbull**: The invariant theory of the quaternary quadratic complex, Part 1. The reduced system. By a reduced system is meant a set of symbolic factors in terms of which any concomitant of the given ground form and of all possible types of quaternary variables, can be expressed. It differs from the ordinary set of factors given by the fundamental theorem for symbolic methods by being easier to handle. The investigation throws light on the properties of the Riemann-Christoffel curvature tensor.

PARIS.

Academy of Sciences, Dec. 5.—**Paul Appell**: The application of the theorem of virtual work to movement with friction.—**Maurice Hamy**: A particular case of diffraction of the solar images at the focus of a telescope.—**de Sparre**: The danger that may arise from cavitation in the case of a sudden stoppage of pumps feeding a main.—**G. Friedel**: The forms assumed by myeline in contact with water. Reply to a criticism by M. Nageotte.—**E. Mathias, C. A. Crommelin, and H. Garfit Watts**: The rectilinear diameter of ethylene. Ethylene obeys the law of the rectilinear diameter. The deviations from the straight line are larger than those for hydrogen and neon, and are of the order of 1 per cent.—**E. Bataillon**: The mitoses of simple activation in crossings of batrachians.—**Ragnar Frisch**: The theorem of determinants of Hadamard.—**Hadamard**: Remarks on the preceding communication.—**Pierre Vernotte**: A property of the method of least squares.—**Mandelbrojt**: Suites of holomorph functions.—**Julius Wolff**: The series $\Sigma A_n/(z_n - a_n)$.—**Henri Cartan**: Some theorems of R. Nevanlinna.—**J. Villey and Ét. Hochard**: A strabometric manograph with deformable electric condenser. An elastic metallic membrane receives on one face the cyclic pressure to be studied, and on the other face a permanent known pressure. The membrane forms one plate of a condenser, and is balanced against a known condenser through an electrometer. The sensibility of this instrument is limited only by the error of reading an ordinary static manometer used to control the readings.—**Henri Bénard**: Vortices in bands and Rayleigh's theory. Description of experiments confirming the theoretical predictions.—**Emile Belot**: The seismicity of the sun and the periodicity of magnetic storms. The lines traced by magnetographs on the earth are regarded as the electromagnetic translation of the curves which would be recorded by seismographs placed at the surface of the sun.—**A. Schidlof**: A construction furnishing the mass of the charged material point in the universe of five dimensions.—**L. Décombe**: Electrified spherical pellicles and spectral series.—**C. Raveau**: The reversible triangular cycle. Demonstration of several classes of thermodynamic relations.—**Mlle. O. Jasse**: A new interferential method of measuring the refractive indices of liquids.—**Georges Simon**: The use of the spectroscope in the regulation of superposition fringes.—**Georges Vaudet**: The spark spectrum of chlorine and bromine in the Schumann region. The lines given extend from wave-length 2252 A. to 1302 A.—**J. Rossignol**: Spectroscopy of the spark of mercury produced in an oscillating high-frequency circuit in permanent regime.—**Salomon Rosenblum**: The powers of slowing down by the atom relative to the α-rays.—**Mlle. C. Chamié**: The phenomenon of grouping of atoms of radioelements. Additional experiments are described showing that the atoms of radioelements can be associated in groups in various media and under varying conditions.—**A. Seyewetz** and **D. Mounier**: The action of light upon nitrated colouring matters. Phenols or amines containing the nitro group turn brown when exposed to sunlight or ultra-violet light. It is probable that a reducing action has taken place, but the presence of the amino group could not be proved.—**Ch. Quillard**: A method of distinguishing aluminium alloys based on the use of *p*H indicators.—**Charles Prévost**: The allyl transposition and the mechanism of esterification.—**Urion**: The preparation of 1, 5-heptadiine and 2, 6-octadiine. These hydrocarbons are produced by the interaction of the dimagnesium derivative of dipropargyl and methyl sulphate.—**Paul Fallot**: The mountainous region between Priego and Cabra (Andalusia).—**L. Gaurier**: A particular form of filling up in some high mountain lakes.—**Adolphe Lepape**: The origin of the radioactivity of the springs of Bagnères-de-Luchon. There is a relation between the radioactivity and the amount of sulphur present in the waters.—**William Herbert Hobbs**: The expeditions to Greenland of the University of Michigan. An account of the work done during the summers of 1926 and 1927. The object of the expeditions was to extend our knowledge of the glacial anticyclone.—**Lucien Daniel**: The variations of the secretory apparatus in various grafted plants.—**R. Dostal**: Morphogenic observations on *Caulerpa prolifera* of the bay of Villefranche-sur-mer.—**J. Dumont** and **B. Ganossis**: The deflocculation and the plasmolysis of the earthy coatings.—**Emile Saillard**: The coefficients of diastatic inversion.—**Louis Bounoure**: The chondriome of the primary gonocytes in *Rana temporaria* and the search for the genital elements in the early stages of development.—**Paul Chabanaud**: The nasal organ of *Solea vulgaris*.—**F. X. Lesbre** and **R. Tagand**: A triple monster of the ovine species. A description of a lamb, born dead, which had one head and neck, was double in the middle and triple below.—**Denis Bach**: The nitrogenous nutrition of the Mucorineæ. The assimilation of uric nitrogen.—**Angel Establier y Costa** and **Charles Kayser**: The effects of puncture of the fourth ventricle: hyperallanturia and troubles of thermal regulation.—**J. E. Abelous** and **H. Lassalle**: The influence of the section of a nerve on the general excitability of the nervous system.—**Michel Polonovski** and **René Hazard**: The action of *N*-methylgranatoline on the circulation, the pneumogastric and the heart.—**Perret-Maisonneuve**: The secretion and utilisation of the wax in the bee (*Apis mellifica*). Bees will utilise any suitable material for making their cells, and the conclusion is drawn from the experiments detailed that the secretion of wax under the normal conditions of existence of the bee is an economical necessity and not a biological function.—**Maurice Piettre** and **André Chrétien**: The influence of some electrolytes on the phenomena of agglutination. Researches on the agglutination of bacilli of the paratyphoid group by specific immunosera. The age of the organism does not appear to be an essential condition, the most important factor being the chemical state of the bacillus.—**A. Blanchetière**: The hydrolysis of ovalbumen by pepsin in its relations with the formation of the diacipiperazines.—**Jean Delphy**: The constitution of the nuclear apparatus in the Infusoria: the Anoplophryimorphs.—**G. Lavier**: Particulars of the nucleus in the trypanosomes of the Brucei group, of recent isolation.—**Raymond Poisson**: A new eccrinid, *Tæniellopsis orchestiæ*, a protophyte parasite of the rectum of *Orchestia bottæ*. Its evolutive cycle.—**Jules Amar**: The laws of pathogenic action.

CAPE TOWN.

Royal Society of South Africa, Oct. 19.—**J. F. V. Phillips**: *Olea laurifolia* Lam. (ironwood): an introduction to its ecology. This is a highly important tree ecologically, sylviculturally, and economically. Despite its slowness of growth and the various disabilities to which it is subject, the species is fully capable of holding its ground in the Knysna forests and even of increasing its frequency if not kept in check. There is a steady demand for the timber.—**H. G. Fourcade**: (1) A new method of aerial surveying: second paper. The adjustment of an aerial traverse to terminal conditions is developed. An instrumental method of transferring, without computations, the vertical point from plate to plate is described, and a simple procedure for determining the directions of successive air bases is worked out. The ground control may be limited to single points at the end of traverses, instead of the clusters of 3 formerly thought necessary for fixing the positions of the terminal pairs of plates. (2) The principal point and principal distance in photogrammetry. The principal distance gives the angular scale of photographs and, in consequence, is a fundamental constant of the photogrammetric camera. The principal point, being the origin from which plate measures must proceed, is equally important. Former methods for determining these constants lacked precision because they depended on linear measurements of a central projection made upon a commercial plate, which usually is by no means plane, and either ignored distortion or treated it as an accidental error.—**P. R. v. d. R. Copeman**: Studies in the growth of grapes (Part 6). The acid-sugar ratio. An expression of the form $y = b/x - c/x^2 - a$ may be used to express the acid y in terms of the sugar x. The constants are affected to a greater extent by changes in locality than by seasonal changes. If r be the ratio acid-sugar, then $rx = b/x - c/x^2 - a$, and therefore the ratio may be calculated from the sugar content of the juice.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 13, No. 10, October).—**J. S. Nicholas**: The application of experimental methods to the study of developing Fundulus embryos. From the time when the embryo of this marine fish has attained a definite form, it can be safely removed from the egg-shell; the technique is described. The embryos so obtained develop in sea water, fresh or distilled water, and were used for experiments. These show that determination of tissues occurs at an early stage.—**J. H. Bodine**: The action of Na, K, and Ca chlorides on the egg of Fundulus. The embryo dissected from the egg is resistant to sodium chloride solution although the larva is killed. Both the other chlorides kill the embryo quicker than the egg, and the larvæ are very sensitive. Mixtures of sodium and calcium chlorides are not toxic for eggs, but very toxic for embryos.—**T. P. Abello**: Absorption of ultra-sonic waves by hydrogen and carbon dioxide. Waves of a frequency of 612,000 per second from a piezo-electric crystal were passed through a tube 5 cm. long and the intensity of the emergent beam was measured by a torsion vane. Plotting percentage volume of carbon dioxide or hydrogen in the air in the tube against the intensity gives points which follow a logarithmic curve.—**W. H. McCurdy**: On the fine structure of some mercury lines.—**Leonard B. Loeb**: On the duration of the existence of doubly charged positive ions in gases, and their detection. A critical discussion of recent results leads to the conclusion that while doubly charged positive ions are undoubtedly generated by the ionising agent in certain cases, they are few in number, and it is doubtful if they exist in the gas as multiply charged ions for sufficient time to be studied as such in ordinary ionic experiments.—**G. A. Miller**: Groups generated by two operators of order three, the cube of whose invariant is invariant.—**R. L. Moore**: Some separation theorems.—**John Belling**: A working hypothesis for segmental interchange between homologous chromosomes. Assuming that a break in the chain of genes of a chromosome takes place when the chain is at maximum extension (leptotene stage), then when two homologous chromosome conjugate, the breaks may or may not coincide. In the former event, should the four ends not be even or a twist have occurred, there is opportunity for interchange as the genes link up again.—**Robert E. Burk**: The heterogeneous thermal decomposition of ammonia in strong electric fields. One method by which a contact catalyst may function is by weakening appropriate bonds in the adsorbed molecules by atomic disturbances, *i.e.* distortion of the electronic orbits by the surface fields of the catalyst. With molybdenum wire 0·005 cm. diameter and fields of 44,000 volts per cm. at the surface, and platinum wire 0·0005 cm. diameter and fields of 150,000 volts per cm. at the surface, no change in rate of decomposition was observed.—**Bernard Lewis**: The photochemical decomposition of hydrogen-iodide; the mode of optical dissociation (see NATURE, April 2, 1927, p. 493).—**Jacob Papish** and **L. E. Hoag**: The detection of uranium by a photoluminescence test. A bead of fused sodium or potassium fluoride, when 'activated' by a trace of uranium, gives a brilliant and distinctive luminescence if illuminated by ultra-violet light or by a condensed iron spark. Columbic acid gives a similar luminescence with sodium but not with potassium fluoride, but the latter is not so sensitive as a reagent.—**Herbert L. Lombard** and **Carl R. Doering**: Cancer studies in Massachusetts. (1) The relationship between cancer and density of population in Massachusetts. The earlier finding of increased cancer death-rate with density of population among natives born of native parents is negatived on making adjustments for age and sex distribution. The statistics for foreigners are insufficient to give significant results, although the cancer death-rate appears to be higher than among natives. Part of the density phenomenon may be due to better facilities for diagnosis.

Memoir 108: Studies of the Influence of Menhaden-Fish Meal on Calcification in Growing Animals. By L. A. Maynard and R. C. Miller. Pp. 23. (Ithaca, N.Y.)

Smithsonian Institution: Bureau of American Ethnology. Bulletin 85: Contributions to Fox Ethnology. By Truman Michelson. Pp. vii+168. (Washington, D.C.: Government Printing Office.) 75 cents.

Annual Report of the Board of Regents of the Smithsonian Institution, showing the Operations, Expenditures and Condition of the Institution for the Year ending June 30, 1926. (Publication 2879.) Pp. xii+561+125 plates. (Washington, D.C.: Government Printing Office.) 1.75 dollars.

Department of Commerce: U.S. Coast and Geodetic Survey. Terrestrial Magnetism. Serial No. 398: Results of Magnetic Observations made by the United States Coast and Geodetic Survey in 1926. By Daniel L. Hazard. Pp. 13. (Washington, D.C.: Government Printing Office.) 5 cents.

CATALOGUES, ETC.

Catalogue de livres anciens et modernes rares ou curieux relatifs à l'Orient. (No. 5.) Pp. 117-180. (Paris: Libr. Adrien-Maisonneuve.)

Sotheran's Price Current of Literature: Catalogue of Science and Technology, No. 8. Annotated and Classified List of Rare and Standard Works on Exact and Applied Science. Part 3: including 12, Mining and Metallurgy. (No. 806.) Pp. 841-928. (London: Henry Sotheran and Co.)

Old and Modern Books: English and Foreign Literature, Modern First editions, Voyages and Travels, Americana. (No. 18.) Pp. 72. (Newcastle-on-Tyne: William H. Robinson.)

A Rough List of Recent Purchases of Valuable Books on Zoology, Botany, the Physical and Mathematical Sciences, Sport, etc. First Portion. (New Series, No. 20.) Pp. 60. (London: Wheldon and Wesley, Ltd.)

Diary of Societies.

SATURDAY, JANUARY 7.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. E. N. da C. Andrade: Engines: Putting the Furnace in the Cylinder (Juvenile Christmas Lectures) (V.).

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (College of Technology, Manchester), at 4.—H. S. Primrose: Electric Melting of Non-Ferrous Metals.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section) (at 36 George Street, Manchester), at 7.

WESTERN JUNIOR GAS ASSOCIATION (at Works of Bath Gaslight and Coke Co.).—W. L. Ashman: Some Notes on Water Softeners and Water Softening.—H. C. Feltham: Future of the Gas Engine.

MONDAY, JANUARY 9.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Dr. J. Horne: Obituary Notice of Laurence Pullar.—Prof. J. Lorrain Smith: Obituary Notice of Prof. Henry Harvey Littlejohn.—Penelope M. Jenkin: Note on the Sympathetic Nervous System of *Lepidosiren paradoxa*.—Prof. D. Noel Paton: Reflex Postural Adjustments of Balance in the Duck.—Dr. E. A. Baker: The Photographic Latent Image as a Phenomenon of Luminescence (third paper).—Edith Philip Smith: A Comparative Study of the Stem Structure of the Genus Clematis, with special reference to Anatomical Changes induced by Vegetative Propagation.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—Capt. P. P. Eckersley: Technical Principles of Broadcasting (Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—A. H. Lee and others: Discussion on Portable Power Appliances.

INSTITUTE OF METALS (Scottish Local Section) (at 30 Elmbank Crescent, Glasgow), at 7.30.—Open Discussion.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Award of Prizes and Studentships; Criticism by L. Sylvester Sullivan on Work Submitted.

SURVEYORS' INSTITUTION, at 8.—C. H. Bailey: The Reports of the Royal Commission on Mining Subsidence.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Dr. T. G. Longstaff: The Nanda Devi Problem.

INSTITUTE OF CHEMISTRY (Manchester and District Section) (at Manchester).—Prof. H. S. Raper: Some Inter-relations of Chemistry and Physiology.

TUESDAY, JANUARY 10.

INSTITUTION OF MINING ENGINEERS (Annual General Meeting) (at Geological Society), at 11 A.M.—Prof. H. Louis: Presidential Address.—Prof. H. Briggs and Prof. H. Louis: The Rhéolaveur Coal-washer in Belgium.—Dr. J. S. Haldane and Dr. R. V. Wheeler: The Use of a Lamp-room Photometer.—T. A. Southern: Life-saving in Colliery Explosions and Fires.—J. P. Rees: The Measurement of Low Air-velocities in Mines.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. E. N. da C. Andrade: Engines: Heat Engines which produce Cold (Juvenile Christmas Lectures) (VI.).

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts) at 5.30.—Dr. L. Dudley Stamp: The Connexion between Commercial Oil Deposits and Major Structural Features, with Special Reference to Asiatic Fields.

INSTITUTION OF CIVIL ENGINEERS, at 6.—Sir Dugald Clerk: Standards of Thermal Efficiency for Internal-Combustion Motors.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—T. R. Thomas: The Effect of Type and Disposition of Machinery on the Strength of Ships.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.—A. C. Banfield: Bridges, Pictorial and Otherwise.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Engineers' Club, Manchester), at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.15.—H. T. Harrison: The Problems of Public Lighting by Electricity.

INSTITUTE OF METALS (North-East Coast Local Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—G. Mortimer: Permanent Mould Casting in Aluminium Alloys.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—C. C. Swatman: Cleaning Mud Gatherings for Diatoms.—M. Burton: Deep Sea Sponges and the Beauty of their Structure.

SHEFFIELD METALLURGICAL ASSOCIATION (Annual General Meeting), at 7.30.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8.—Sir William J. Pope: Colour Photography (Lecture).

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. W. Brown: Theories of Suggestion.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at Broadgate Café, Coventry).—M. Platt: The View-point of the Owner Driver.

INSTITUTION OF THE RUBBER INDUSTRY (Liverpool Section) (at Common Hall, Hackins Hey, Dale Street, Liverpool).

WEDNESDAY, JANUARY 11.

ROYAL SOCIETY OF ARTS, at 3.—Prof. A. Smithells: Flame (Dr. Mann Juvenile Lectures) (II.)

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—G. M. Lees: The Geology of South-Eastern Arabia.

OVERHEAD LINES ASSOCIATION (at Institution of Electrical Engineers), at 5.30.—Major T. Rich: French Regulations.

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 6.—Roger T. Smith: The Effect of Acceleration and Deceleration on the Wear of Railway Track.

GLASGOW UNIVERSITY ALCHEMISTS' CLUB (jointly with R.U. Chemical Society), at 7.30.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Branch, Graduate Section) (at Middlesbrough), at 7.30.—G. Booth: Colliers.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Institute of Chemistry), at 8.—J. R. Nicholls: The Determination of Small Quantities of Benzoic and Cinnamic Acids, with some Notes on the Colorimetric Determination of Salicylic Acid.—The Preservatives Determination Committee of the Chemists of the Manufacturing Confectioners' Alliance, Food Manufacturers' Federation: A Rapid Method of Determining Sulphur Dioxide, and Four Additional Papers.

ROYAL SOCIETY OF MEDICINE (Laryngology, Medicine, and Odontology Sections), at 8.15.—Special Discussion on The Influence of Naso-oral Sepsis on the Lungs and Gastro-Intestinal Tract. Openers: E. D. D. Davis and C. A. S. Ridout (for Section of Laryngology); Dr. R. A. Young and Dr. T. I. Bennett (for Section of Medicine); J. G. Turner and A. Bulleid (for Section of Odontology).

CERAMIC SOCIETY (at North Staffordshire Technical College, Stoke-on-Trent).—Prof. E. L. Collis: Dust Inhalation with special reference to Silicosis.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section).—S. R. and E. R. Trotman and J. Brown: Action of Acids on Wool.

THURSDAY, JANUARY 12.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—Prof. W. E. H. Berwick: Soluble Sextic Equations.—J. Wishart: A Problem in Combinatorial Analysis giving the Distribution of Certain Moment Statistics.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group), at 7.—Informal Meeting.—E. A. Bierman: Colour Plate Technique, with Display of Autochromes through the Lantern.

INSTITUTE OF METALS (London Local Section) (at 83 Pall Mall), at 7.30.—Dr. G. D. Bengough: Corrosion, with Special Reference to Standard Tests (Lecture).

ROYAL SOCIETY OF MEDICINE (Neurology Section) (at National Hospital, Queen Square, W.C.), at 8.—Clinical Meeting.

INSTITUTION OF MECHANICAL ENGINEERS (Glasgow Branch) (at Glasgow).—E. G. Herbert: Cutting Temperatures: Their Effect on Tools and on Materials.

INSTITUTION OF MECHANICAL ENGINEERS (Leeds Branch) (at Leeds).—L. H. Fry: Some Experimental Results from a Three-cylinder Compound Locomotive.

INSTITUTION OF MECHANICAL ENGINEERS (Cardiff Branch) (at Cardiff).—Prof. C. J. Hawkes: The Marine Oil-Engine (Thomas Lowe Gray Lecture).

OIL AND COLOUR CHEMISTS' ASSOCIATION (at 8 St. Martin's Place, W.C.).—R. G. Daniels: Some Points in the Manufacture of Zinc Oxide.

INSTITUTION OF THE RUBBER INDUSTRY (Birmingham and District Section) (at Grand Hotel, Birmingham).—F. W. Lanchester: India-rubber as an Auxiliary to Suspension.

FRIDAY, JANUARY 13.

ROYAL ASTRONOMICAL SOCIETY, at 5.—E. A. Kreiken: Some Remarks on the Orbits of Spectroscopic Binaries.—A. T. Doodson: Application of Numerical Methods of Integration to Tidal Dynamics.—Nizamiah Observatory, Hyderabad, Occultations of Stars by the Moon, 1926 January–1927 September.—Hong Kong Observatory, Transit of Mercury observed at Hong Kong, 1927, Nov. 10.—S. Rosseland: On the Time of Relaxation of Closed Stellar Systems.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Newcastle-upon-Tyne), at 6.—J. Calderwood: Diesel-Engine Drive for Generators and other Auxiliary Machinery on Board Ship.

PHILOLOGICAL SOCIETY (at University College), at 8.—Dr. W. Perrett: Greek Music.

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section), at 8.—W. S. Duke-Elder: Factors controlling Intra-ocular Pressure.—M. L. Hine: Report on a Case of Neuro-fibromatosis of the Eyelid and of an Artificial Eye which burst in the Socket.—E. Wolff: A Bend in the Sixth Cranial Nerve and its Clinical Significance (Anatomical Specimen).

JUNIOR INSTITUTION OF ENGINEERS.—N. E. Jackson: Air Conditioning: A General Survey of its Uses and Application.

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Chemical Society).—H. R. S. Clotworthy: The Manufacture of Artificial Silk: with special reference to Viscose.

SATURDAY, JANUARY 14.

INSTITUTION OF MECHANICAL ENGINEERS (Bristol Branch) (at Bristol).—Prof. C. J. Hawkes: The Marine Oil-Engine (Thomas Lowe Gray Lecture).

EXHIBITION.

JANUARY 10 TO 12.

ANNUAL EXHIBITION OF THE PHYSICAL SOCIETY AND THE OPTICAL SOCIETY (at Imperial College of Science and Technology), from 3 to 6 and from 7 to 10.—Discourses at 8:—

Jan. 10.—A. Whitaker: Progress in the Recording and Reproduction of Sound.

Jan. 11.—V. E. A. Pullin: Recent Application of X-Rays.

Jan. 12.—Dr. J. W. T. Walsh: Artificial Daylight.

Editorial and Publishing Offices:

No. 3037, Vol. 121]

Education and Industry.

"INTELLECTUAL forces are . . . broken and unco-ordinated. Stores of rich material and reservoirs of valuable experiences have been accumulated in national and local collections, and in the professional and other scientific and commercial associations. But the channels of communication . . . are scanty. . . . Each of some 140 local education authorities provides technical education suitable to its own local needs and limited by a generous or a parsimonious financial policy. Is the total effect a patchwork or an organic whole? Wasteful or efficient? . . how can industrial organisations . . . and local industrial experience be brought into closer co-operation with those who provide the funds and control the schools and colleges? . . . Finally, there is left the question of which Central Authority is to direct the operations of the intellectual forces. . . . Some half-dozen government departments are engaged, directly or indirectly, in the application of education and research to industrial (including agricultural) problems. But there does not appear to be any minister in any department whose duty it is to see that these departmental efforts are duly co-ordinated."

These extracts from a recently published Report[1] give some indication of the problems which faced the committee responsible for its compilation. The Report falls into three main divisions. The first, from which we have already quoted, briefly summarises the history of the wide problem of education and industry. Inevitably it recapitulates the arguments and conclusions to which other bodies, dealing with similar tasks, have been forced; arguments which are so simple that it is a matter for astonishment that they should fail to be grasped and applied. Their base has been outlined in these columns over and over again when we have urged a revision of traditional educational philosophy. It is that within a relatively brief period we have passed from a non-scientific to a scientific age. The face of industry has changed: its conditions have radically altered; and these conditions and changes have had their reflection in the ordinary national life. "Life itself has been extended," says the Report. "The engineer, the chemist, and the medical officer have broadened the basis, protected our food supply, and safeguarded the public health. The statistician and the press register daily records of the temperature, the pulse, and the blood-pressure of national existence. Science has given us a new era."

The second division assumes a particularly high value. It is a report collated by the Federation of British Industries, and may therefore be regarded as the industrial view of the Committee's problems. Too frequently, when efforts have been made to bridge the gap between education and industry, has the charge been made that it is the prejudiced voice of the educationist which speaks, and not the voice of those daily in practical touch with industrial and commercial activities. This division of the Report to which we now refer is, we understand, solely the work of the F.B.I., and is the result of "replies of a number of Associations and also individual opinions of manufacturers in all trades throughout the country." At least in one respect it ought to destroy the notion, still cherished in some academic circles, that industry refuses to recognise its own weaknesses, and shelters them behind loud criticism of the educational system. For, although it does not fail to criticise "the incomplete nature of elementary education" and asks for closer consideration to the question of securing suitable teachers in technical institutions (here, indeed, another popular charge against industry is upset, for "it is suggested that the emoluments are in some cases not sufficient to attract those best equipped for the training of our technical school students"), it states quite frankly that a complete expression of industrial opinion is difficult to obtain, since, "generally speaking, there has been no formulated policy regarding technical education, and in many trades it has not even been considered."

---

[1] Report of an Inquiry into the Relationship of Technical Education to other Forms of Education and to Industry and Commerce. Pp. 60. (A.T.T.I. Offices, 29 Gordon Square, London.) 1*s*.

Clearly, it is difficult for busy manufacturers to prepare detailed educational schemes for their individual business, and the very sensible suggestion is therefore made that a memorandum should be prepared "covering the main features desired in any technical training. This memorandum, being of a national character, could then be expanded by trades in consultation with the technical authorities into comprehensive courses." Although industry may regard itself as unable to give a complete solution to the educational problems it desires to have solved, there are two outstanding points in its contribution to the Report. First, in reply to the direct question, "Do you regard technical education as essential to the conduct and development of your industry?" the replies showed "an overwhelming body of opinion as to not only the desirability, but the absolute necessity of an adequate technical education." Then comes the suggestion, which shows clearly that no mere vocational training in separate processes is confused with the term 'technical education': to be complete, it "must envisage not only the technique of production, but also the selling and distribution and the interlocking of these three aspects with costing and other statistics leading to management and administration."

The third division of the Report consists of summaries of the answers received in reply to special *questionnaires* sent to local education authorities, technical institutions, and schools of art in England and Wales. Since these summaries embody the results of thirty-eight searching questions, space precludes any attempt to deal with them at length. It is to be noted, however, that the difficulty of recruiting staffs composed either of teachers experienced in industry who understand the art of teaching, or experienced teachers with a wide knowledge of industry, presents a special problem.

While advisory committees are the usual means of linking schools and industries, employers serve on many governing bodies, but employees (as such) rarely do so. This question of a stronger link was further emphasised when information was sought as to whether technical education should be organised by local education authority areas or by industrial areas (*e.g.* cotton, heavy chemical trades, coal mining, printing, etc.). The replies included such suggestions as (*a*) a joint board of local education authorities and representatives of industry (over industrial areas); (*b*) the centralising of teaching at new faculties of modern universities; (*c*) advisory committees; (*d*) central colleges for advanced courses (costs to be apportioned over the area served); and (*e*) inter-county arrangements. Obviously, however, the value of technical colleges as places of research is of vast importance in the further co-ordination of education and industry, and here the Report expresses astonishment at the rarity of any relationship with research institutes. There are, of course, outstanding examples, such as the close relationship at Manchester and Bolton with the British Cotton Industry Research Association; at Bradford and Nottingham with the British Research Association for the Woollen and Worsted Industries; and at Loughborough with the Iron and Steel Institute.

Much remains to be done, however, in this direction. Outside consulting work done by colleges helps to some extent, but that there does not appear to be any general method of its organisation, and that it is subject to varying conditions and regulations in different places, is shown by the dissimilar arrangements for the allocation of fees charged to authority and teacher. But the main obstacle to research appears to lie in the conditions of the Teachers' Superannuation Acts. "The

London County Council suggests that the reaction on both staff and students, of actual contact with works problems, is of considerable importance; that the arrangements in force regarding superannuation . . . makes official recognition of research impossible." The importance of this matter is shown strikingly by the fact that, prior to present regulations, this authority had in view the adoption of a rule making the carrying out of some research work by individuals a condition of employment. Not only in London is research appreciated. A "considerable amount is conducted" at Loughborough, and the "governors are anxious to develop" it; in Leicester it is strongly "encouraged"; "every facility" is afforded in Nottingham (University College); at Bristol (Merchant Venturers) it is "encouraged in all departments"; Bradford provides "ample facilities and every encouragement"; Hull Education Authority is "considering relieving staff from teaching duties to undertake research."

In spite of the valuable information which is presented by the Report, however, it is, at first sight, disappointing in that it puts forward no definite conclusions. Certainly, in a brief paragraph the essentially liberal qualities of technical education are emphasised, but no attempt seems to have been made to sketch out the kind of new educational philosophy which must, in view of our changing and complex modern life, take the place of the older traditions. Present relationships between technical schools, secondary schools, and universities are shown rather by implication than by definite clear-cut statement, and there appears to be no suggestion as to what should be the next step. After collecting such valuable evidence, the Committee seems content to submit "that the facts set out in this Report and in the documents which accompany it, justify its appeal for taking stock of the present condition of technical education, its relationship to general education, and, above all, of the obstacles to closer co-operation with industry."

We presume that this appeal is made to the Board of Education, and we are, of course, aware that already an influential deputation, led by Lord Gainford, and consisting of representatives of education, employers, and trade unions, has already presented the Report to the President of the Board, who has promised to see the Committee again after he has read it. But if the next move lies with the President, it becomes difficult to reconcile that with industry's view that "it would appear to be of very doubtful value to press for any further Government activity in the immediate future until efforts have been made to establish the closer relationship" of technical education and industry. Clearly, the Committee has itself established unique machinery; for we do not remember when, in the educational and industrial history of Great Britain, so many powerful bodies were drawn together to attempt the solution of this imperative question. We would therefore have expected that some suggestion might have been made as to how this present machinery might have been used to reach the ends desired.

When, however, we consider the history of this movement to link education and industry, we realise that the Committee may have done wisely in avoiding the temptation to map out definite schemes. The problem is so wide and far-reaching, and already some aspects of it have been discussed by the Hadow, Malcolm, and Balfour Reports. We recall, too, that when the present Committee submitted its purpose to the President of the Board of Education more than two years ago, the latter hinted that until he had before him the findings of all the committees concerned he would not be able to give any pronouncement concerning the steps which ought to be taken to accomplish the end all of them had in mind. The Hadow and the Malcolm Committees have already presented certain definite proposals. The Balfour Committee, like the present Committee, hesitated, in the first part of its industrial survey of "Factors in Industrial and Commercial Efficiency" (see NATURE, April 9, 1927, p. 517 *et seq.*), to make any definite recommendations. Its aim was rather to assemble and analyse facts and tendencies and so to prepare the way for further intelligent study of issues which are so supremely important to national well-being. Definite recommendations from various committees are apt to be mutually cancelling.

Still, there are now four reports available for the President of the Board of Education (our own comments on the Hadow Committee appeared in NATURE of Feb. 5, 1927), and we shall await with some anxiety any official pronouncement of their effect upon future progress.

In the meantime we congratulate the Committee responsible for the Report before us, not only on the collection of its invaluable evidence, but also upon its own unique constitution. We would emphasise that that constitution includes, in addition to all types of teaching bodies and learned and professional organisations, the Federation of British Industries and the General Federation of Trade Unions. Surely here is machinery which must not be allowed to cease functioning.

The Nature of Solutions.

The Scientific Work of the late Spencer Pickering, F.R.S. By Prof. T. M. Lowry and Sir John Russell. With a Biographical Notice by Prof. A. Harden. Pp. ix + 247. (London: Harrison and Sons, Ltd., 1927.) 4*s*.

THE origin of this work is the following clause in the will of the late Mr. Pickering, who died in December 1920:

“ I give to the Treasurer of the Royal Society of London, Burlington House, Piccadilly, free of duty, the sum of £1000 upon trust to procure the writing and publication in book form of an account of my work in pure science or of such part of it as may seem suitable for such treatment.”

Spencer Umfreville Pickering, to use words written of Fleeming Jenkin, by R. L. Stevenson, was “ a man much more remarkable than the mere bulk or merit of his work approves him.” An aristocrat by birth and breeding, in appearance and manner, of very determined individuality, he was yet one of the gentlest and most sympathetic natures possible in face of the few whom he knew towards whom he was drawn. No cold recital, such as that before us, of his feats with thermometers—which were stupendous, both the thermometers and the feats—and in disputing the discontinuities in curves with the ungodly or of his freakish treatment of fruit trees can give the faintest picture of the man, of the artistry in his composition and the rare nobility of his character. You saw and felt ancestry in him. To understand him, the family history must be studied—in the autobiography which he lovingly edited, written by his mother, also but incidentally in the works of his younger sister, Mrs. W. A. Stirling, especially in “ William de Morgan and his Wife ” (Thornton Butterworth, Ltd., London, 1922), in part the life of their elder sister, Evelyn, an appreciated painter of most beautiful decorative pictures in the manner of the Burne Jones school, who married (1887) William de Morgan, the noted potter and novelist, son of Augustus de Morgan, professor of mathematics in University College, London. Pickering, therefore, in middle life, was associated with a highly original artistic circle; he was himself an accomplished musician and a lover of art and literature.

“ Of the intellectual qualifications of the Pickerings as a race,” Mrs. Stirling remarks, “ it is possible to speak with an unusual degree of certainty from a remote period.” “ I apprehend,” said Sir Isaac Heard, Garter, King of Arms, writing to their grandfather, “ that there is scarcely any family in England so well descended as yours and who can so well authenticate it, not merely by the pedigree but by the records of the kingdom, combining ancient nobility and royalty.”

Pickering's father was a Q.C., Recorder of Pontefract, Attorney-General for the County Palatine and sometime Treasurer of the Inner Temple. At Eton, he was known by his long hair and his good looks were proverbial. He became a great friend of young William Ewart Gladstone, who for many years afterwards kept up a correspondence with him in which he expressed himself enthusiastically Tory in principle; only his change in politics, later in life, made a severance between the friends. At the Bar he was noted for his eloquence, his penetration and his sense of humour. When past-forty, he married the daughter of Lady Elizabeth Spencer Stanhope. Mrs. Pickering, on her father's side, came of two families—the Spencers and the Stanhopes—who had been settled in Yorkshire since the Middle Ages—a race of fine old country squires. The story of the family has been told by Mrs. Stirling in “ Coke of Norfolk and his Friends.” Lady Elizabeth was a direct descendant of Thomas, Earl of Leicester, the great dilettante of the mid-eighteenth century. Thomas Coke, who on a barren part of the Norfolk coast erected a palace of Italian art and filled it with choice treasures of antiquity, was the possessor of a master mind and left the impress of genius on all with whom he dealt. His nephew and successor, the father of Lady Elizabeth, better known as ‘ Coke of Norfolk,’ although his best energies were concentrated on agriculture and questions of practical utility, exhibited gifts which equalled those of his predecessors.

Mrs. Pickering, we are told, was a woman of exceptional intellect, whose cleverness lay in deep thought and extensive study. She early devoted herself to the development of her children's minds. Recognising how much she had suffered from the narrowing influence of governesses, at her instance, masters came and went to the house, the most efficient that money could procure. From the first, brother and sister (Pickering was three years Evelyn's junior) profited by the same instruction—learning Greek and Latin, besides French, German and Italian, classical literature and mythology, the mother inspiring in them actual love of knowledge as distinct from the drudgery of lessons. Mrs. Stirling's description of her method is most fascinating:

“ In all her children, a recollection of their early years was connected with what proved to them the happiest period of each day, the hour when they were summoned to a flower-laden room and their mother read aloud to them from some volume of absorbing interest. To her, reading aloud was a gift; she delighted in it; and her clear, musical voice ever after seemed indissolubly linked with the books which she first made them love. The range of literature thus covered was wide and comprehensive; but where the books which were available on any particular subject did not convey the exact impression she wished to produce, she herself supplied the deficiency. Thus history, she found, was apt to be written in a fashion which failed to grip the imagination of a child, so she wrote a history of England for her children of arresting interest, dwelling on the vital facts to be remembered and making the whole so graphic that it became to her small listeners a living actuality teeming with romance. Scientific books, too, she found were inevitably couched in language ill-adapted to the intelligence of her audience, so she wrote for them volumes which read like a fairy-tale: she described the wonderful prehistoric world, where Man was not but where strange beasts abounded and the dim antediluvian forests which æons of time had fashioned into coal, pieces of which were then burning in the grate of the cosy little room; she dwelt on the discoveries of astronomy, the grand riddle of the stars which looked like glittering dust strewn over the dome of heaven; the marvels of chemistry, of geology, of the practical application of many recent discoveries. She wrote fluently, without effort and with few erasures; indeed, the charm and the facility of her style hint what success in the literary world would have been hers had she not confined her talents solely to this labour of love."

What a lesson in method for mothers and teachers generally!

Pickering in his nursery days was a child who arrested attention by his beauty; his hair of bright gold fell in a luxuriant mass of long curls. Even when these were shorn later on, curls still clustered thickly over his shapely head, so that at Eton, on account of his good looks and classical features, he was known as the young Antinous. The picture given as a frontispiece to the volume, though a likeness, in no way does him justice. He entered Balliol College, Oxford, in January 1877, where he remained until the Lent term 1880. Even as a schoolboy he was devoted to chemistry and had his laboratory in the home of the family in Bryanston Square, where all his original work was done up to 1902. Several of his papers had been published in the *Journal of the Chemical Society* before he left Oxford. His chemical precocity is clearly apparent in all of these, especially in the study of the interaction of copper and sulphuric acid and of the loss of sulphur by cupric sulphide.

I learnt to know Pickering at the time of his first appearance at the Chemical Society, of which I was a secretary. We became fast friends and I was witness of and almost a partner in all his attempts to force his work and views on 'The Nature of Solutions' into notice. In this he was both determined and uncompromising—he was so sure of his work and so entirely obsessed by honesty of scientific purpose.

We are carried back to the days when the study of the properties of solutions was beginning to attract the attention of workers generally—to the summer of 1887, when the great Russian chemist, Mendeléeff, visited Great Britain and captured us all by his picturesque appearance and charm of manner. Mendeléeff was present at the British Association meeting in Manchester in 1887. He there gave an account of his views on solutions in a short paper on "The Compounds of Ethyl Alcohol with Water," in which he showed that the curve representing the change in density of solutions of alcohol in water as the concentration was varied could be resolved into several linear terms by plotting the first differential coefficient ds/dp against p. He regarded the points of intersection as *loci* of hydrates. I at once secured the paper from him for the Chemical Society and it appeared in the October number of the *Journal*. Not only so. I induced my pupil Holland Crompton, an able mathematician, to apply the method to Kohlrausch's most striking curve showing the variation in electrical conductivity of solutions of sulphuric acid and to other electrolytes. His paper was read at the December meeting of the Society and after it in the *Journal* was printed a "Note on Electrolytic Conduction and on Evidence of a Change in the Constitution of Water," in which I summarised my views on electrolytic conductivity.

Crompton found that the Kohlrausch curve was resolved only at the second differentiation. I therefore claim, following Mendeléeff, to have started the curve-hunt. Pickering at once joined in and became an enthusiastic user of the method. Having been engaged in studying the thermal behaviour of salts towards water and thereby led to the discovery of breaks which he had supposed to be due to changes in the state of hydration, he was in a highly receptive state of mind and henceforth devoted himself to intensive study of the subject. He made an extraordinarily careful and probably unsurpassable examination, particularly of the densities, of solutions of sulphuric acid and developed a method of analysing his curves with the aid of a bent lath. He came to the conclusion that the curve could be split up into a great number of intersecting elements and urged that the points of intersection—no less than seventeen in sulphuric solutions—were indications of the formation of distinct hydrates.

There was universal disbelief in the validity of Pickering's conclusions and particularly of the method he used. Rücker, the physicist, was strongly opposed to it. When I consulted my mathematical colleague, Henrici, the authority on graphics, at the time, he gave the opinion that, if the results could be shown by independent methods to be valid, no objection could be taken to the method. Otherwise, it was not possible to pronounce for or against it. Pickering had to fight his way to publication through the by no means encouraging reports of referees chosen from outside the chemical circle and therefore credited with superior authority—but coldly aloof from chemistry, if not unsympathetic. "You can't go outside the opinion of a man like Rücker, you know," was the kind of argument used by objectors. The work was so obviously good, however, so exact and thorough, that he could not well be denied: still, the treatment he received soured his proud nature; he felt he was not being helped, that no sympathy was accorded him. Moreover, he was up against the great wave of fashion which soon set in through Ostwald's persistent advocacy of Arrhenius. No one was prepared to reason.

A so-called discussion took place at Leeds, at the British Association meeting in 1890, which, at the time, struck me as being singularly hollow, lacking both in breadth and logic. Ostwald's contentions were chemically absurd. I notice that, at the recent meeting, the president of Section B referred to Pickering and me as having been 'diehards' at the time. Seeing that we had so recently unfurled our banners, which were quite distinct—I was never an advocate of a mere hydrate theory, at least in Pickering's sense—and that Arrhenius's speculation was also of recent birth, in its accepted form younger than ours, we should have been 'die-easy's' had we lowered our flags at Teutonic challenge, seeing how entirely our antagonists avoided the chemical issue—and have so done to the present day. As Bancroft recently admitted, the function of water in solutions still has to be considered and properly evaluated. Although, forty years ago, I could picture it as having a constitution, it is still worshipped, in all the text-books, as Aitch-too-oh!

It is not difficult to understand that Pickering should have been anxious to have judgment delivered upon his work after his death. The question is—to what extent is the attempt made to do him justice satisfactory? In my opinion it is neither adequate nor properly judicial but lacks both the breadth and critical acumen the subject demanded. Pickering, I am sure, intended and desired that the situation in general should be considered—not merely the validity of *his* work and arguments. His joy was in exact work and his desire: to establish truth.

Pickering directed in his will that *an account* of his work in *pure science* should be procured and published in book form. Instead, we have two accounts, one of his experiments at Woburn on fruit farming, which certainly was not work in *pure science*. This occupies fully one-third of the book. It is written by Sir John Russell with his accustomed skill and ability to summarise an agricultural situation. Sir John makes clear the departure Pickering made from the practice of fruit-growers, the main results of his trials and observations, the new issues raised—in a very interesting manner. We may thank him for the summary.

What Pickering had in mind and desired, I feel sure, was an extensive monograph on "The Nature of Solutions," in which proportionate notice was taken of his work and its bearings. Instead, we have a mere appreciation of the work he did and of his method of interpreting curves, together with an account of his chemical work in general in the form of brief abstracts which read as though they were prepared for the Chemical Society. A wrong note is struck, in the introduction, in the statement, "For the purpose of preparing this memoir, I have received two bound volumes of 'Scientific Papers,' etc." It was the reporter's duty to consider not merely what was put into his hands but the subject at large. Pickering asked for something much broader than a mere consideration of his scientific papers: he would not have assigned £1000 for this purpose. He was a gentleman and never sought the limelight—nor was it ever flashed upon him, so little able were we to appreciate the character of his labours and the example he gave. Even the Chemical Society took no notice of him. In science, as elsewhere to-day, the sensational counts; the value of prolonged exact inquiry is seldom recognised.

Prof. Lowry was peculiarly fitted to appraise the value of Pickering's physical studies of solutions on the practical side, as he is a most accomplished worker himself in the physical field. He does justice to his subject in this respect and finally gives *his opinion*, that Pickering was justified in his conclusions that solutions exhibit a multitude of discontinuities but takes the view, common among us at the time the work was under discussion, that these are not to be taken each as evidence of a distinct hydrate.

Prof. Lowry leaves the great problem of the nature of solutions undiscussed—makes no attempt, in fact, to bring under notice the vast amount of work done during the past fifty years. He has nothing to say of the solvent—of water itself. He shows that he has neither imagination nor a free mind, no sense of logic. He is willing to accept any freakish new view as it comes along, such as the chess-board conclusion: that there is no bond of union between the constituents of common salt. He declares himself a syncretist by the confession (p. 32), that early in his career "he was faced with the necessity of finding for his own use a scheme which should be compatible with the two rival points of view [dissociation and hydration]. This he found in the idea that *both* views were correct, that their incompatibility was imaginary and not real, and that the hydration of the ions not only provided a way of reconciling the two theories of solution, but also supplied a motive for the electrolytic dissociation of a salt."

The fact is, *pace* Arrhenius, Ostwald and Co., we know nothing of the processes at work in solutions—it was for this reason that Pickering wished to have the subject fully discussed. We need to have all the *facts* assembled and contrasted: then perhaps we shall see a way through the maze. Actually, the facts never are considered but instead various fancy sums are worked on paper and chemical considerations are left out of account, probably physical as well. As Lodge put it in 1889, "chemists have permitted themselves to be run away with by a smattering of quasi-mathematics and an overpressing of empirical formulæ."

The physical chemist has been neither chemist nor physicist at heart. The late Prof. Bateson, I believe, always advocated the view that the production of a 'mutation' involved the loss of a factor: the mutation from chemist to physical-chemist certainly seems to have involved the loss of the primary factor in chemistry: chemical feeling. We have to recover this or chemistry will be imperilled. At least, we should be honest, consider *cons* as well as *pros*, not merely formulate conclusions without any semblance of logic behind them. It was this dogmatic tendency that my friend Pickering always strove to combat. A true analysis of his efforts has yet to be given.

Himself he fell a victim to the modern disease, physical measurement — unavoidable, doubtless, like measles, yet like this disease often followed by severe after-effects, especially loss of the imaginative faculty. He became so much the slave of subminute precaution, that chemical artistry went out of him. He so lived the life of the recluse, in his aristocratic contempt of the Little-enders, that we never recovered him to that broader service in chemistry of which he showed himself capable particularly in his first essay and in his devotion to the fruit of the soil.

HENRY E. ARMSTRONG.

Isaac Newton.

Isaac Newton, 1642–1727. A Memorial Volume edited for the Mathematical Association by W. J. Greenstreet. Pp. vii + 181 + 9 plates. (London: G. Bell and Sons, Ltd., 1927.) 10*s*. 6*d*. net.

THE genesis of this volume is explained in the preface. The Council of the Mathematical Association desired to commemorate the bicentenary of the death of Newton by a special number of the ***Mathematical Gazette***. The response to the editor's appeal for contributions was generous and varied. It soon became clear that the limits of a single number would be far exceeded and that interest in the material would not be confined to members of the Association. Hence it was decided to issue it as an independent book. It has taken the form of a symposium of nineteen separate chapters. Mr. Greenstreet is indeed to be congratulated upon the distinguished names that answered his appeal.

Each contributor chose his own subject and treated it in his own fashion. The absence of a connected plan reduces any review to little more than a list of titles. In some of the chapters Newton's name is not much more than a text, and it is the preacher's own views that are heard from the pulpit, which may be more or less interesting, according to one's point of view. In this class are Prof. Eddington's treatment of Absolute Rotation, and Prof. Forsyth's discussion of the Problem of Least Resistance. Perhaps Prof. H. E. Armstrong's chapter on the Forms of Carbon and Chemical Affinity should be put under the same class. Others again, though they cannot be said to contain any matter that is not already in print and quite accessible, show a deep and just appreciation of Newton's point of view, admirably presented. Newton's Work in Optics, by Prof. Whittaker, is of this kind, and Prof. Proudman on Newton's Work on the Theory of the Tides. Rather more might be said of the Rev. J. J. Milne's article on Newton's Contribution to the Geometry of Conics, and Prof. H. Hilton's Newton on Plane Cubic Curves. The lifelong special studies of both authors make their chapters more than historical enumerations. If ever the often desiderated general editor of Newton should appear, he will be very grateful for such articles.

There are several others, indeed, that he will not afford to put by. Mr. D. C. Fraser on Newton and Interpolation is a direct contribution from the author's researches in the Newton MSS. at Trinity College. Mr. J. M. Child on Newton and the Art of Discovery, though not quite of the same class, is truly illuminating as to the kind of tentative construction through which Newton gradually made his way to the binomial theorem and other discoveries. It shows how often the greatest minds climb upwards step by step, rather than leap. Plagiarism in the Seventeenth Century, and Leibniz, provides Prof. L. J. Russell with an interesting theme. Prof. A. E. Heath on Newton's Influence on Method in the Physical Sciences, and Prof. E. A. Bartt on the Contemporary Significance of Newton's Metaphysic, are contributions on the philosophical side. Mr. J. A. Holden, treating of Newton and his Homeland, gives some interesting particulars, but repeats uncritically many exploded fables. Prof. G. N. Watson gives an account of Trinity College in the Time of Newton, but curiously omits to mention his laboratory. Mr. H. Zeitlinger gives an interesting conspectus of the Bibliography of Newton's writings, containing much that would not be easy to find elsewhere. The late Dr. J. L. E. Dreyer was overtaken by his last illness before he was able to complete a promised contribution to the volume, but is represented by some letters he collated from Corpus Christi College, Oxford.

To complete the list of contributions, Prof. D. Eugene Smith contributes three chapters, the first containing Two Unpublished Documents of Sir Isaac Newton, and the second and third on Portraits and Portrait Medals. All three are valuable. But we cannot agree with the pride of place he awards to the portrait by Gandy which is reproduced as a frontispiece. There is one truthful portrait of Newton at least—the death mask, faithfully rendered in Roubiliac's statue. It shows that Newton, like many men of genius, had a receding forehead, with rather blunt features of extreme decision. Gandy has followed the usual convention of a dome-like brow and has given the face delicate features and a general neurasthenic air.

The volume concludes, for no particular reason, with a Latin composition "supposed by the Rev. and learned Dr. Francis Lockier, Dean of Peterborough; reduced into an epitaph by the Sec. of the Gentleman's Society at Spalding," which is in the usual eighteenth century style of such compositions, with its pointless adulation and its long lines and its short lines extending almost *ad infinitum*.

It cannot be said the volume is adequate to the occasion, but what volume would have been? It is an interesting book, for the most part very readable and containing quite a proportion of matter that is either new or well worthy of recall.

European Echinoderms.

(1) *Handbook of the Echinoderms of the British Isles.* By Dr. Th. Mortensen. Pp. ix+471. (London: Oxford University Press, 1927.) 38*s.* net.

(2) *Les échinodermes des mers d'Europe.* Par Prof. R. Koehler. (Encyclopédie scientifique: Bibliothèque de Zoologie.) Tome 2. Pp. ii+339+9 planches. (Paris: Gaston Doin et Cie, 1927.) 35 francs.

WITH the completion of Prof. Koehler's account of the echinoderms from European seas, and with Dr. Mortensen's English work on those from British seas, the European, and particularly the British, student is fully provided, so long as he takes both books. Dr. Mortensen nowhere precisely defines what he means by British seas, but since he includes the greatest depths, and since, as Prof. Koehler points out, forms found at those depths generally prove to have a relatively wide distribution, therefore, on the probable chance that the British list may be greatly extended, he has comprised in his account the whole of the echinoderm fauna known from the north-east Atlantic. In this respect Dr. Mortensen is more comprehensive than Dr. Koehler; thus, among crinoids he describes the deep-sea forms *Democrinus parfaiti*, *Ilycrinus carpenteri*, *Monachocrinus* 3 spp., *Atelecrinus helgæ*, *Pentametrocrinus atlanticus*, *Trichometra delicata*, and *Orthometra hibernica*; some of these are mentioned, but none described, by Dr. Koehler.

The other classes show the same difference of treatment by the two authors. On the other hand, Prof. Koehler describes twenty-seven species confined to the Mediterranean, many of which are not mentioned by Dr. Mortensen. Eight species marked by Koehler as special to the Mediterranean do, however, find place in Mortensen's book as Atlantic forms. There are also eleven Arctic species described by Koehler, but not mentioned by Mortensen. It follows that, for a complete account of the European echinoderm fauna in the widest sense, both books are needed.

(1) Dr. Mortensen's "Handbook" is on the same lines as his "Pighude" in "Danmark's Fauna," reviewed in NATURE, Nov. 22, 1924, but naturally includes more species. The tonic accent on the Latin names, which we approved, was apparently beneath the dignity of the Oxford University Press. On the other hand, the index is said to give the English and popular names, but we do not find such obvious examples as 'rosy feather-star,' 'cushion-star,' 'cross-fish,' and 'piper,' not to mention many that might have been taken from Forbes's "British Starfishes." Dr. Mortensen does not seem so familiar with that classical work as one would expect: in referring to a famous passage he gives it on the authority of G. H. Lewes. Forbes used the word 'star-fishes' in a very wide sense, and there is something to be said for Dr. Mortensen's use of 'sea-stars' to denote the 'true star-fishes' as Forbes called them.

In his classification of the Asteroidea, Dr. Mortensen advances a step beyond his Danish book, now giving three orders: Phanerozonia, Spinulosa, and Forcipulata. For the Ophiuroidea he does not see his way to use any of the new classifications, and the orders of Echinoidea also remain as before. Among Holothurioidea the main change is the transference of the Synallactidæ from the Elasipoda to the Aspidochirota. The diagnoses throughout are restricted to those characters necessary when only species from the north-east Atlantic are considered. Special attention is paid to larval forms, parasites, and other ecological features. It seems a pity that a book so admirably adapted to the needs of the working zoologist and the serious amateur should have been produced in a style more suited to the shelf of a reference library than to the pocket or the cabin work-table: it weighs 2 lb. 6 oz.

(2) Prof. Koehler's two volumes (the first was reviewed in NATURE of May 23, 1925) weigh together only 1 lb. 9¼ oz., and each will go comfortably into a side-pocket. The whole work costs less than a quarter the price demanded for the English book. The present volume contains the sea-urchins, crinoids, and holothurians. With the last class Dr. Koehler has an intimate acquaintance, and his discussion of some involved questions of specific identity is very detailed. A distinctive feature of this volume is the chapter on geographical distribution and the lists of species according to the following regions: littoral Arctic, abyssal Arctic, littoral Boreal, littoral Lusitanian, abyssal Boreal and Lusitanian, Mediterranean. Still, however, we miss from both books any comparison of the fauna with that in other regions.

F. A. BATHER.

Our Bookshelf.

Root Development of Vegetable Crops. By Prof. John E. Weaver and William E. Bruner. (McGraw-Hill Publications in the Agricultural and Botanical Sciences.) Pp. xiii+251. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1927.) 20*s.* net.

CONSTANT endeavours to improve crop growth have led to the accumulation of a mass of information concerning the aerial parts of plants and the factors influencing their development. Our knowledge of the underground parts, whether roots or stems, has not increased at the same rate, largely owing to the mechanical problems which render investigation difficult and laborious. This is the more to be regretted, in that the environment of the root can to a large extent be controlled by cultivation and manuring, thus giving scope for the direct amelioration of growth conditions, whereas climatic and light factors, which directly affect the aerial parts, are beyond control by human agency.

Prof. Weaver and his colleagues have already done much to extend our knowledge of the roots of field crops, and in the present volume they continue the investigation into the root system of vegetable crops, thus benefiting the gardener or small grower as well as the farmer. Typical root systems of the more important vegetable crops are described at various stages of growth, and scattered information from various sources is correlated with the results obtained.

The book is rendered more valuable to the practical man by the discussion of root development in relation to cultural practice, in which the advantages and disadvantages of the different soils, methods of cultivation and manuring are considered in relation to individual crops. Knowledge of root systems should enable the grower to combine his various crops to the best advantage, in order that the soil may be adequately filled with roots, drawing evenly on the available plant food, without undue competition in any one place combined with untapped areas elsewhere on the field. The many illustrations are from drawings made *in situ* as the roots were excavated, and the surprising extent of the root systems, even of such a small crop plant as the common radish, gives food for much thought to all, from the amateur gardener to the scientific plant physiologist.

The Theory of Integration. By L. C. Young. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 21.) Pp. viii + 53. (Cambridge: At the University Press, 1927.) 5s. net.

THE integral calculus was founded two thousand years ago by the Greeks, who applied it with much success to the determination of areas and volumes. Its first appeal to the mathematical world was that of a new and powerful instrument of calculation. When interest was re-aroused in science after the Middle Ages, the infinitesimal calculus developed rapidly under the stimulus of new symbolism, progress being mainly in manipulation until the end of the eighteenth century. Up to then there was little advance on the rigour of the ancients, which, though possibly misplaced, was very severe. There followed a period of criticism, initiated by Cauchy's theory of limits, when the logical ideas at the foundation of the subject were examined. It was found that many of the results obtained by the methods of the calculus would not stand the scrutiny of the new analysis. Such ideas as the treatment of infinite series by the processes of finite algebra were found to need revision.

A still more refined outlook on functions of a real variable was introduced by Cantor in his theory of sets of points. This has been made the foundation of the modern theory of integration by Lebesgue, W. H. Young, and Hobson. In the tract before us, Mr. Young gives a successful exposition of this branch of his father's work in a style that shows much of the vigour and freshness of youth. Although the author stresses the fact that he assumes a minimum of mathematical knowledge, many readers will find the logical sequence of ideas embodied in the tract to be hard reading. Integration is here treated as a subject in itself, apart from differentiation, and the usual fundamental theorem of integral calculus is not mentioned. The complete absence of algebraic manipulation and of even the best-known integrals must be accepted as a tendency of an extensive branch of present-day mathematics, but will appear to some readers as novel. Still, the fact that it is possible to develop a theory of integration on these lines is a striking testimony to the power of the modern treatment. W. E. H. B.

The Performance and Design of Direct Current Machines. By Dr. Albert E. Clayton. (Engineering Degree Series.) Pp. xi + 418. (London: Sir Isaac Pitman and Sons, Ltd., 1927.) 16s. net.

A VERY large number of books have been published on the design of electrical machinery. Most of these contain formulæ which are not much greater help to the designer than rule-of-thumb methods. To give accurate formulæ is impossible, as the reluctance of the magnetic circuit is in general a variable quantity, and the permeability of iron is also variable. The magnetic flux produced by a current is only proportional to the current when the magnetic field has constant permeability, and this assumption can only be made by assuming that the dynamo is built without iron. To assume also that the end connexions of an armature coil have constant 'inductance' is scarcely justifiable. Notwithstanding these assumptions and many similar ones, designers do find formulæ a real help. They are kept on the right lines by comparing their theoretical calculations with the results obtained by experiment. For a particular make of machine, they are soon able to predict the performance with quite satisfactory accuracy.

Dr. Clayton's book is intended for use primarily by students in universities and technical colleges. The reader is supposed to have an elementary knowledge of electrical engineering principles. A balance has been struck between the requirements of a practical designer and the requirements of a student looking forward to an academic examination. For the latter, the numerous examples given at the end of the book, many of which are taken from the University of London papers, will be found very helpful.

The Neurotic Personality. By Dr. R. G. Gordon. (International Library of Psychology, Philosophy and Scientific Method.) Pp. x + 300. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., Inc., 1927.) 10s. 6d. net.

DR. GORDON has presented us with a most excellent book, in which he pleads strongly for a rational viewpoint towards the psychoneuroses. He refers frequently to emergent evolution which forms the basis of his previous book on personality. He gives us a very sound review of the Freudian, Adlerian, and Jungian attitudes towards the neurotic personality, and stresses particularly the need for the study of each case entirely on its merits and its treatment without any preconceived notions, using both pure medicine and psychotherapy; in other words, the application of calm common sense.

The author's opinion that the neurotic never becomes insane will not meet with universal approval. At the same time, he qualifies his opinion by stating that many early cases of insanity are difficult to differentiate from neurosis; in other words, if an apparent neurosis develops into insanity, it was obviously not a neurosis.

Winterstein's Die Alkaloide: eine Monographie der natürlichen Basen. Zweite neu bearbeitete Auflage von Dr. Georg Trier. Erster Teil. Pp. 356. (Berlin: Gebrüder Borntraeger, 1927.) 18 gold marks.

THE first part of the new edition of this standard work on the alkaloids is devoted entirely to a treatment of various classes of bases the constitutions of which have in most instances been settled ("die chemisch näher bekannten Basen"). The sectional headings are (1) aliphatic bases (including amino-acids), (2) aromatic and fatty-aromatic bases, (3) amides, (4) urea derivatives (including the purines), (5) heterocyclic bases of the pyrrole-pyridine group (including coniine, pelletierine, atropine, cocaine, and nicotine). There is a historical introduction of 34 pages, but no title-page, summary of contents, or index is supplied at this stage in the publication.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Transmission of Sonic and Ultrasonic Waves through Partitions.

IN other places I have pointed out that recently devised methods of experiment with ultrasonic waves offer possibilities for a more complete experimental solution of certain acoustic problems than can conveniently be carried out with low or ordinary pitched sounds. A case in point is the reflection from and transmission through material partitions of acoustic waves.

The late Lord Rayleigh, following the classical methods of Green, offered a mathematical treatment of the problem of reflection of longitudinal waves and their transmission through partitions; but the theory until recently had never been tested directly by any experiment. The theory is exact enough for practical purposes, and is analogous to the optical problem of the passage of light waves through a parallel-sided transparent plate. On applying the appropriate boundary conditions in the acoustic problem, it can be deduced that when a train of plane longitudinal waves impinge at perpendicular incidence on a parallel-sided, infinite partition, of homogeneous material, obstructing the waves in a medium, the ratio (r) of reflected to incident energies is given by

$$r = \frac{\left(\dfrac{V\rho}{V_1\rho_1} - \dfrac{V_1\rho_1}{V\rho}\right)^2}{4\cot^2 2\pi\dfrac{d}{\lambda_1} + \left(\dfrac{V\rho}{V_1\rho_1} + \dfrac{V_1\rho_1}{V\rho}\right)^2}.$$

Here ρ and ρ_1 stand for densities, and V and V_1 for velocities in the medium and partition respectively. Thickness of partition is d, λ_1 is the wave-length in its material. It follows that when $V\rho = V_1\rho_1$, or what amounts to the same thing, if $\rho\lambda = \rho_1\lambda_1$, λ being the wave-length in the incident medium, r is zero; or in the words of a convenient rule, remembered by a few experimenters, "when the *mass of a wave-length* in incident and reflecting media is the same, reflection is nil and transmission is perfect." Given a solid and large enough plate of any material as reflector, the relation above indicates that the proportion of energy reflected depends on the thickness of the reflector. It is quite possible for a thin plate to cut off more energy than a thicker one, or a thick plate to let through more energy than a thinner one. For if d above equals $n\frac{\lambda_1}{2}$, where $n = 0, 1, 2, 3$, etc., corresponding thicknesses of plate will be integral numbers of half wave-lengths, in which cases the reflection will be minimum and transmission maximum; if $d = (2n+1)\frac{\lambda_1}{4}$ . . ., corresponding thicknesses will be integral odd numbers of quarter wave-lengths and reflection will be maximum and transmission minimum. There is nothing in the theory to prevent its validity at any frequency high or low, but it must be noticed that all considerations of energy dissipation, *i.e.* absorption, within the partition are neglected.

When due precautions are taken, probably the most convenient and accurate method of measuring ultrasonic energy is by the torsion pendulum, the method having been adapted first by Langevin. Types of pendulums and mountings as used by me have been described in *Trans. Roy. Soc. Can.*, 19, 179; 1925. The vane of a torsion pendulum placed in the track of an ultrasonic beam is itself a small plate reflector of the waves; in consequence its readings should depend on the thickness of the vane, and the pendulum itself may be made to yield information concerning the reflection.

In a short paper (*Trans. Roy. Soc. Can.*, 21, 115; 1927), describing preliminary experiments carried out some years ago by Mr. J. F. Lehmann and myself, it was shown, by using ultrasonic waves of frequency 135,000 cycles per second travelling in water and striking lead pendulums, that the reflection from the lead was a maximum and transmission a minimum at a thickness of vane about a quarter wave-length; and reflection was a minimum and transmission a maximum at a thickness of half a wave-length. Later, many other experiments of this kind, in which different materials and different frequencies were employed, were carried out by Mr. D. K. Froman and me, with results all similar to the original ones. Recently Mr. D. O. Sproule and I performed a series of *direct* experiments on the same problem, in which the energy transmitted through a metallic plate, intercepting at right angles the path of an ultrasonic beam in water, was measured with a torsion pendulum placed in the 'ultrasonic shadow' behind the plate. The particular frequencies employed were 300,000 and 528,000 cycles per second. Arresting facts like the following were observed. With a frequency of 300,000 cycles per second, a 2 mm. plate of type-metal, which was the obstructing material used in these experiments, could block off completely the ultrasonic beam, while a plate two or four or six times this thickness allowed the larger part of the energy to emerge through it. It was quite clear that, at plate thicknesses of an odd number of quarter wave-lengths, reflection was maximum and transmission minimum, while at thicknesses of a small integral number of half wave-lengths the reverse was the case and nearly all the incident energy got through.

One significant condition prevails in all this work—the velocities as deduced from plate thicknesses work out very appreciably higher than that calculated from Young's modulus and the density. The reasons for this result will later be explained elsewhere. Papers on the experiments referred to are being prepared.

The theory outlined by Rayleigh is straightforward, since analogous theories are accepted for other and all types of vibratory motion. In the case of acoustic waves the half wave-length is the thickness requisite for a *resonant* longitudinal vibration of the reflecting partition. We can imagine a partition or plate of this thickness picking up the incident energy, setting itself in resonant vibration, and handing on the energy through the medium on the other side. At a quarter wave-length thickness the plate, so far as concerns its own vibration, is most inert, offers the most impedance to the impinging waves, and reflects them back.

Considerations of resonance would apply also to partitions which shut off waves of ordinary sound, if the practical conditions usually holding were appropriate. No doubt they do apply in a few rare cases, for example, where the partition can execute 'drum-like' vibration or vibrate flexurally. It may be recalled that Watson (*University of Illinois Bulletin*, 19, 127) once reported a very interesting and apparently strange experimental result. He blocked up the doorway of a room containing a source of sound with cork boards and on the outside measured the sound energy which got through. He found that a thickness of 1¼ in. of the cork reflected less and transmitted more sound than did either ¼ or 2¼ in. On trying obstructions of *paper-lined* hair-felt he obtained a similar result. It is likely that some condition of resonance of the partition explains the fact of minimum reflection and maximum transmission at the intermediate thickness.

In materials generally used for sound absorption, such as hair-felt, the sound is transmitted mostly through pores; but the late W. C. Sabine, on finding that the absorbing power of some felts was *a maximum for certain frequencies*, thought it possible that the felt absorbed partly by the dissipation of the waves in its pores and partly by the yielding of its mass as a whole. In an interesting paper on the transmission of sound through hair-felt by Davis and Littler (*Phil. Mag.*, 3, 177; 1927) the thickness-transmission ratio curves showed not much sign of curvature to indicate any condition of partition resonance at the frequencies used in the experiments; but the authors point out that such is the result only for porous material, and that probably the case would be different with partitions transmitting "an appreciable fraction of the incident sound by diaphragm-like vibration."

The Evidence for Hybrid Vigour in Insects.

IN several reports on the introduction of *Aphelinus mali* into New Zealand and its colonisation, Dr. R. J. Tillyard has stated that by crossing three different strains from America he has produced a more vigorous strain which is now established over the greater part of New Zealand. To quote from one of his articles—"The story of how the three strains of *Aphelinus* were crossed, producing the very vigorous strain which is now being distributed all over New Zealand, is too long to tell in detail here, but the main points may be mentioned."

This aspect of applied ecology or biological control is of great importance to entomologists, and therefore it is necessary to examine the evidence upon which this statement is founded.

Turning to Dr. Tillyard's reports, we find that he received six boxes of parasitised aphis from America, two from Washington State, two from Connecticut, and two from Arkansas. These three consignments were placed together in one breeding box and eighteen specimens hatched. By his own account only five specimens, two females and three males, which hatched out between Feb. 6 and Feb. 15, formed the parents of all his future colonies used in establishing the insect in New Zealand, where they have multiplied and spread and been of great benefit to the country.

The fact that insects are collected from three places, although considerable distances from one another, does not carry with it the fact that they are distinct strains. It is necessary to show some slight biological difference between them. As all the material received was placed in the same breeding box, it is impossible to say whether the eighteen specimens hatched from only the material from one or from two or from all three localities. It is quite possible that they hatched from material from the same locality, and even that they represent one family, being brothers and sisters. Any superiority that might be observed might then be due to an unconscious selection of a superior genetic mutation.

Is there any superiority in the present New Zealand strain, or is their flourishing condition only due to the same factors as caused their host (the woolly aphis) to flourish, namely, congenial climatic conditions, abundance of food, and absence of enemies? Judging by our work in the Hawaiian Islands, I should say that it was so. The idea which underlies this subject is hybrid vigour, and it would be of importance to establish by proper experiments how far this applies to insects. The evidence we have in Hawaii is more in the negative than in the affirmative. In the case of certain Coccinellidæ, inbreeding in captivity has led to reduced fertility, but here we are not quite sure how much of this is due to inbreeding and how much to the conditions of confinement. In a number of cases a small colony has been received from one locality and the insect established in the islands; after many years (some more than twenty) they are as vigorous as ever and show no signs of failing. In certain cases of small parasitic Hymenoptera the insect has carried on generation after generation parthenogenetically, only one or two males ever having been seen out of many hundreds of thousands of individuals. Our examples are not confined to Hymenoptera, but include Diptera, Coleoptera, and Neuroptera.

Most insects that become established in a new country and become a pest are introduced as small colonies from one locality, and in most cases are only introduced once, so that there must be a great amount of inbreeding in a few years. Unfortunately they show no lack of vigour.

The question of hybrid vigour in insects therefore stands in an uncertain condition, and any statement must therefore be supported by evidence for the species in question; no general conclusion can be laid down. In the case in point the necessary evidence is lacking.

While it may be a good policy to get several consignments from different localities when trying to introduce and establish an insect, this is not often possible. Also, the dangers which cannot be entirely eliminated when bringing in a colony are thereby increased. For the latter reason we have always tried to establish our introductions in Hawaii from a single small colony which can be handled more easily. Unfortunately this cannot always be done.

The Radiation from Explosions of Carbon Monoxide and Oxygen to which Hydrogen has been added.

THE speed of explosion of mixtures of carbon monoxide and oxygen is accelerated by the addition of water or substances containing hydrogen, as was shown by Dixon. The acceleration of the speed is invariably accompanied by a reduction in the emission of radiant energy and, vice versa (Garner and Johnson, *Phil. Mag.*, 3, 97; 1927). The radiant energy emitted from these explosions consists mainly of two bands with maxima at 2·8μ and 4·4μ, which are the emission and absorption bands of carbon dioxide. The emitters of this radiation are the molecules of carbon dioxide which have been set in vibration and rotation by the chemical energy liberated during the explosion.

Experiments by Johnson (unpublished) have shown that about 10 per cent. of the total chemical energy of the explosion is emitted as radiation when a mixture of dry carbon monoxide and oxygen is exploded in a long cylindrical bomb 1 inch in diameter. This is reduced to 2·5 per cent. when 1·9 per cent. of water is present. Since the flame of the moist gases is hotter than that of the dry gases, the radiation cannot be entirely black body. At least 7 per cent. of the chemical energy of the dry gases is emitted as chemiluminescence.

Further experiments on dry explosive mixtures to which varying percentages of hydrogen are added, have thrown light on the nature of the effect. The results are shown in the accompanying diagram (Fig. 1). The currents generated in a thermopile when the radiation from an explosion falls on it, are given as ordinates and the percentage H_2 as abscissæ. The radiation falls very sharply on the addition of 0·07 per cent. H_2, and is still falling slowly when 2 per cent. of this gas is present.

The hydrogen was introduced into an equimolecular mixture of carbon monoxide and oxygen as electrolytic gas.

Since hydrogen has no absorption bands between 2μ and 6μ, it is clear that the reduction of radiation is not due to absorption in front of the explosion wave. It is also unlikely that the reduction is due to the absorption by water vapour formed in the wave front, for the relation $\log R'/R_0 = kx$ does not apply. (R' is the radiation emitted in the presence of x per cent. of hydrogen, and R_0 is the radiation from the dry gases.)

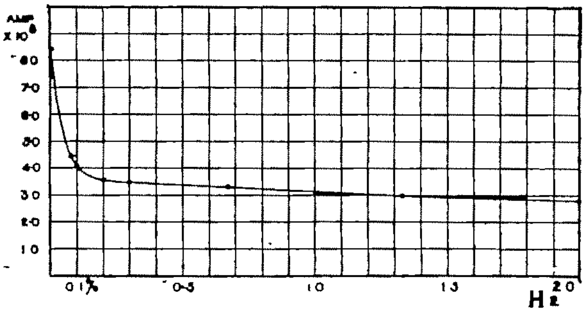

FIG. 1.

When the form of the curve is known with greater exactitude, it should be possible to elucidate the nature of the mechanism by which this reduction is brought about, whether it be due to collisions of H_2O, H_2, or H, with the activated molecules of carbon dioxide, or to some other cause.

Subsidiary Rectangles as applied to the Formation of Magic Squares.

WITH non-consecutive numbers it is possible to make an 'associated' rectangle 8 × 3. It is not possible to do so out of the first 24 consecutive numbers. In using this 'associated' rectangle 8 × 3 to form a magic square also 'associated,' and 'pandiagonal' with subsidiary rectangles 8 × 3, it is further necessary that the 3 diagonals one way should also sum to the same amount as the rows. This is so in the following rectangle, where the rows and the diagonals from left to right sum each to 120 and the columns each to 45.

1	23	19	24	22	9	20	2
16	12	5	13	17	25	18	14
28	10	21	8	6	11	7	29

By means of this rectangle two formative rectangles can be made according to De la Hire's method, one 24 × 3 for the index numbers with 7 replicas, and one for the radix numbers 4 × 24 with 5 replicas. The resultant magic square will be both pandiagonal and associated with 24 subsidiary rectangles 8 × 3, each of whose 3 long rows will sum to 3480 and each of whose 8 short columns will sum to 1305. The 24 rows, 24 columns, and 48 diagonals of the square will sum to 10,440. The intervals for the radix numbers I have taken at 30 instead of 29 for ease of calculation.

The above is the smallest rectangle that can be constructed, consisting of 3 rows, that will give this dual requirement, namely, to be associated, and for the diagonals one way to sum to the same amount as the rows; 4 × 3, 5 × 3, 6 × 3, and 7 × 3 are unable to provide such rectangles without repeating some numbers. This can be proved by algebra.

In the case of 6 × 3, however, the requirement is not necessary, as squares can be formed in other ways. I give the following examples to demonstrate this:

4 × 3

7	⑧	⑭	3
4	⑭	②	12
13	②	⑧	9

32 × 24

5 × 3

⑤	9	14	⑪	1
4	10	8	6	12
15	⑤	2	7	⑪

40 × 24

㉔	29	14	⑫	11
5	1	18	35	31
25	㉔	22	7	⑫

90 × 54

6 × 3

79	30	⑤	32	19	(75)
36	29	67	13	51	44
⑤	61	48	(75)	50	1

240 × 120

7 × 3

14	⑩	33	30	㉖	12	1
5	20	11	18	25	16	31
35	24	⑩	6	3	㉖	22

126 × 54

These rectangles are all associated and have their diagonals from left to right summing to the same amount as the rows, but they all repeat numbers in certain places. If in these places numbers are repeated they are not difficult to construct.

With rectangles with 4 rows the necessity for the diagonals one way summing to the same amount as the rows does not arise, but rectangles 6 × 4 for order 24 are not the smallest that will produce associated squares with subsidiary rectangles 6 × 4. Order 20 can comply with subsidiary rectangles 5 × 4, the whole square being pandiagonal and associated. But order 24 can be composed of 24 rectangles 6 × 4, each one of which is associated and the whole square pandiagonal. This is impossible with subsidiary rectangles 8 × 3 in order 24 or with subsidiary rectangles 5 × 4 in order 20.

The Palæolithic Implements of Sligo.

I THINK that Prof. Macalister and his colleagues have quite fairly stated their opinion (NATURE, Dec. 31, 1927) upon the geological aspect of the sites examined by Mr. Burchell in Sligo. So far as I am concerned, I do not feel entitled to discuss or argue upon the details of this aspect of the matter, for the reason that—as I made clear in my original note in NATURE—I have not yet visited the sites in dispute. I have, however, had abundant opportunities for making an examination of the specimens collected by Mr. Burchell, and of subjecting them to a prolonged and careful examination; and I entertain no doubt whatever that these specimens are humanly flaked, and that their forms and method of flaking are such as were in vogue in Early Mousterian-palæolithic times. Further, I am of opinion that no natural force—or combination of natural forces capable of flaking stone—such as fortuitous pressure, percussion, or thermal action, could in any circumstances produce these forms. This is my sincere belief, and it is because I possess it that I consider it my duty to support Mr. Burchell in this matter.

In these discussions I am always prepared, and perhaps prefer, to stand unaided, and I do not wish, or feel it to be necessary, to call others to my support in this instance. But in the interests of scientific truth it is needful again to direct attention to the fact that every well-known and competent archæologist to whom the Sligo specimens have been shown has, without exception, or any hesitation, accepted them as the work of man. I cannot doubt but that if Prof. Macalister and his colleagues examined these specimens they would also agree with this conclusion. It is because I am convinced that the Sligo material is of human origin I am compelled to conclude that the geological views of Prof. Macalister and his colleagues regarding the Rosses Point site are incorrect. The specimens, too, found by Mr. Burchell embedded deep in Boulder Clay at Ballyconnell, though, I admit, not so conclusively of human agency as those from the other sites, are, I believe, nevertheless artificial, and exhibit the same technique as those discovered at Rosses Point and elsewhere.

Sun Images through Window Glass.

Sunlight comes in through an east window and falls upon the whitened wall of a room; a blind is drawn so as to stop the sunlight except for two vertical strips about two inches wide. The two strips of light seen on the wall are not of even illumination, but consist of a series of distorted images of the sun overlapping each other throughout the whole length of the strips. A 'control' to the observation is made by pulling the window down at the top; the overlapping images are not seen now; this is shown in part A of the photograph, which is separated by the horizontal framework of the window from the part B, in which are the 'through the window' images.

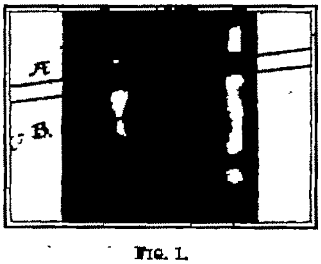

Fig. 1.

The glass is evidently responsible for the effect, though to the naked eye or touch, there is nothing unusual about it.

Perhaps some readers of Nature would suggest an explanation of the observation.

Red Sensitive Photoelectric Cells.

We have found that it is possible to make photoelectric cells of the Elster-Geitel type sensitive to the extreme red, and having a colour sensitivity approaching that of the eye much more nearly than those used at present. The new cells have a limit above $700\mu\mu$ and a very useful sensitivity at $650\mu\mu$; their sensitivity extends also to the violet limit of the visible spectrum, and their total sensitivity to white light is of the same order as that of existing cells.

These cells are not yet marketed in the ordinary way, but we could make a limited number of them available to those who have serious use for them. Inquiries should be addressed here.

Though our process for making these cells works consistently, we do not profess yet to understand it completely. If we described it, we might insist on unessential rather than essential details; and accordingly prefer to postpone a description until our investigations have progressed further.

The 'Green Flash.'

If in my letter in Nature of Dec. 3, I am understood to have suggested that the green flash seen at sunset had no cause other than a physiological one, I withdraw any implied or hinted suggestion in that direction; for it is evident that a great weight of authority is in favour of a physical cause. My letter, indeed, admitted the likelihood of greenish atmospheric effects; but I wished to contribute a simple fact of observation, which suggested to me—and still suggests—that a suddenly disappearing light may stimulate a momentary green sensation in some persons, even when atmospheric and other conditions for actual colour are absent.

It was, I admit, rather hasty to send a letter on so small a point; but readers of Nature may be glad of the consequent reiterated assurances of high meteorological authorities in the issue of Dec. 17 that the solar occurrence of the phenomenon is objective.

The Two Calories.

Much confusion is caused by the use of the word calorie in two different senses—one to signify the amount of heat required to raise the temperature of one gram of water 1° C., and the other to represent what is really a kilocalorie, or the amount of heat required to raise 1000 grams of water 1° C. The only difference between the means of distinguishing the two units is that the large Calorie is spelt with a capital initial letter, and unless great care is taken this may be set up as a 'lower case' letter by the compositor. May I suggest that the confusion could be avoided—at least so far as the printed word is concerned—by spelling the large unit with a capital letter K, thus, 'Kalorie.' The use of the letter 'k' in this way is in conformity with the principle adopted in the designation of metric units generally.

Marsh Gas from Plants.

In Black's "Lectures on the Elements of Chemistry," published in 1803, there occurs the footnote in reference to marsh gas (spoken of by Black as 'inflammable air'): "The *Dictamnus Fraxinella* emits it from its flowers in such abundance in a calm evening, that it may be set on fire by a candle, nay, take fire of itself."

I shall be very glad if any readers of Nature can give me information which will enable me to trace this statement to its source, or any information whatever on the point.

Natural Steam Power Developments at Larderello.

THE problem of utilising the earth's internal heat is no new one, but the general attention of scientific workers and of technologists has been directed to this most interesting topic in a more special manner during these last few years, since a practical application of geothermal energy has been successfully achieved at the Boracic Works of Larderello, in the neighbourhood of Larderello, in Tuscany. This plant, which was originated and brought to its present satisfactory state of development by Prince Piero Ginori Conti, was briefly described in NATURE of Jan. 12, 1924. A few additional details as to further results obtained will doubtless be welcomed by many readers of this journal.

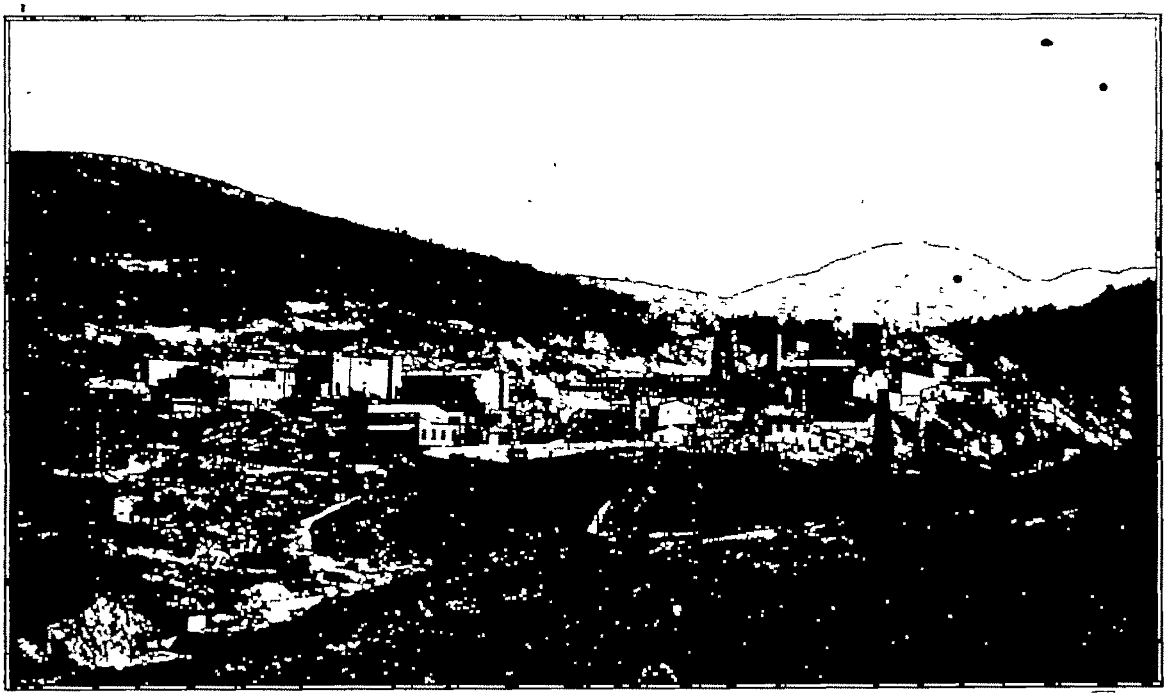

FIG. 1.—General view of the Larderello works.

The fumaroles of Tuscany, better known under the local denomination of *soffioni*, are a notable example of the only form of volcanic activity which is suitable for exploitation, active volcanoes being evidently quite out of the question—at least so far as our present means are concerned. It has been proposed to sink tubes into the hot soil surrounding certain volcanoes, but such schemes do not appear to be practical, as experience has proved that heat transmission, even from incandescent lava, is exceptionally poor, so that enormous heating surfaces would be required to obtain a sufficient quantity of heat to be worth utilising. This observation applies to schemes depending on the utilisation of the geothermal gradient, as by sinking wells to considerable depths in order to reach high temperatures.

Natural steam springs, or fumaroles, are therefore, at the present stage of our experience, the only efficient source of natural heat supply. Very interesting discussions have arisen as to the origin of natural steam such as occurs in California, Oregon, Chile, New Zealand, Java, and Tuscany, where steam springs or fumaroles appear to be a phenomenon allied to vulcanism, but not entailing the immediate neighbourhood of a volcano. Thus, for example, the Tuscan *soffioni* appear to be connected with the trachitic eruptions which took place in central Italy in the latter part of the Tertiary Period, but the traces of these eruptions are found at considerable distances from the spots where the fumaroles are situated. These fumaroles differ, therefore, from those which abound near Vesuvius, Etna, and several other active or quiescent volcanoes, notable among others being those of the "Valley of Ten Thousand Smokes" in Alaska, which issue from the imposing masses of matter erupted from the Katmai volcano, covering a very large area of territory. This latter class of fumaroles is less accessible to investigation, but in some cases, such as the *solfatara* of Pozzuoli near Naples (which is not in the immediate vicinity of Vesuvius, but situated in the crater of an extinct volcano), experiments can be made. A scheme for utilising the *solfatara* of Pozzuoli is being studied.

Modern theories as to the internal structure of our planet lead us to consider that the origin of volcanic phenomena should be traced to magmatic deposits which underlie the upper crust of sedimentary rocks, and in some instances are situated at no very great depth below the surface. The steam which is present (either in its proper form, or dissociated in its component gases) in all volcanic manifestations is mainly the result of crystallisation of such glassy siliceous magma: phreatic or surface waters, penetrating to adequate depths, are in many cases present and condense the magmatic steam, thus forming almost all the ordinary thermal springs, though the presence of phreatic or surface waters can be traced also in the steam of fumaroles. This theory is supported by geophysical evidence, and has been amply illustrated and discussed in more than one instance, and notably in the case of the fumaroles and thermal springs which abound in the United States. Identical conclusions had been arrived at as a result of the geophysical studies carried out on the district surrounding Larderello, under the patronage of Prince Ginori Conti.

The *soffioni* of Tuscany have been utilised since 1818 for the extraction of boric acid, the presence of which in the waters resulting from the condensation of the natural steam was discovered in 1777, but the production of mechanical power by means of these *soffioni* was begun only in 1904. The first machine with which Prince Ginori Conti made his experiments was a very small cylinder engine which he fed with the volcanic steam used, up to that date, only for heating purposes in connexion with the chemical works and especially with the apparatus for concentrating boric waters. This first experiment was a very important one, as it proved the possibility of working continuously in such conditions with an engine. A slightly larger engine was afterwards tried, with excellent results, and a further step was taken in 1913, when a 250-kw. turbine was installed.

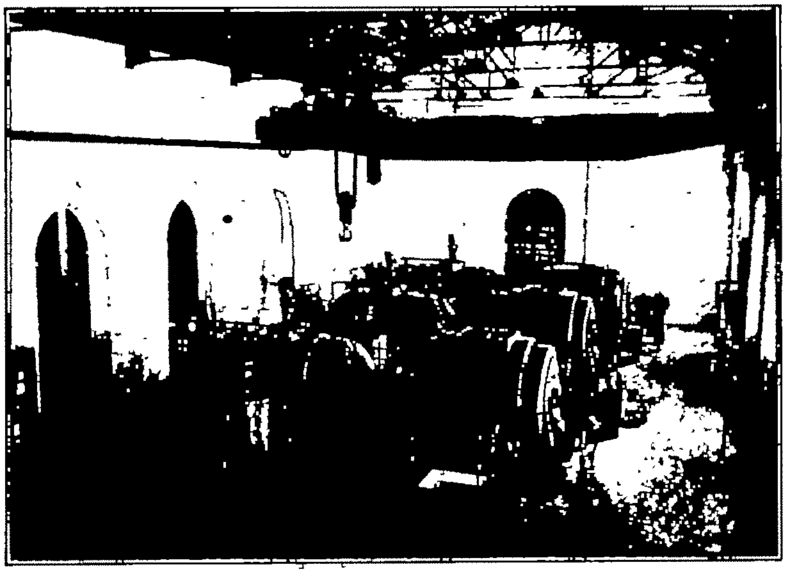

Fig. 2.—The turbine room at Larderello; three turbo-alternators of 2500 kw. each. The turbines are fed with volcanic steam which has been stripped of about 90 per cent. of the accompanying gases.

The steam of the Tuscan *soffioni*, besides boric acid and other substances, including ammonia, is accompanied by a certain percentage of gases, mainly carbon dioxide, with minor quantities of hydrogen sulphide, some methane, hydrogen, nitrogen, and oxygen, and smaller quantities of argon and helium. The presence of such non-condensable gases would have proved a great hindrance to the efficiency of the condensing apparatus required in connexion with turbines, and it was therefore decided to heat, by means of the volcanic steam, appropriate evaporators generating pure steam for feeding the turbines. The same method was adopted when, in 1916, three 2500-kw. turbo-alternators were put up at Larderello. This system, though theoretically correct, did not give very good results in practice on account of leakages often occurring in the evaporator tubes, through which the gases found their way into the turbines and the condensers, greatly reducing the vacuum which is essential to the efficiency of the low pressure turbines (0·25 atm. eff.) used at Larderello.

Considerable improvement was obtained by doing away with the evaporators and substituting, in their stead, special depurating apparatus which eliminates about 90 per cent. of the gas. Such depurators, which are extremely simple, are working most efficiently at the Larderello power station. The non-condensable gases are sent on through pipes to a special department of the chemical works, where carbon dioxide is separated and liquefied: part of it is used at Larderello, together with ammonia which is obtained from the volcanic steam, to make carbonate of ammonia. The depurators also yield a considerable amount of boric waters which are utilised in the chemical department, which, by concentrating the liquors and allowing the acid to crystallise by cooling, extracts boric acid.

More than 5000 kw. is now generated at the Larderello power station, but in the near future three units will be running instead of two, thus adding a further 2500 kw.

The Larderello wells were giving, in the beginning of 1927, more than 120,000 kgm. of steam per hour, but quite recently an exceptionally powerful well was struck, yielding more than 60,000 kgm. of steam per hour at a pressure of 2 atm. eff., so that the supply of steam may be considered as superabundant until sufficient depurators and turbines are installed to deal with it. These very remarkable results are due to the improved methods of drilling which have been gradually introduced. The making of steam wells is an operation which calls for a very careful technique, which can only result from extensive practice in dealing with volcanic soil; it is not exempt from risks, and skilled labour is required, as accidents are not uncommon, steam being sometimes found quite suddenly.

Regular drilling in the volcanic soil of Larderello was begun so far back as 1836, when steam was merely used for its boric acid content, but the old wells were of small depth and their diameters were also small. Gradual improvements were introduced and outputs of 25,000 kgm. per hour were obtained from single wells when the power station was built; but far better results followed about three years ago at the Castelnuovo works, about 3 miles south of Larderello, where about 60,000 kgm. per hour were given out by a new well at 1 atm. eff., while considerable outputs were available from the same well at a pressure of 3 atm. At the older wells, the output falls rather rapidly as the pressure increases. The pressure of a well attains its maximum when the well is closed down, while the gradual opening of the head valve lowers the pressure as the output increases. Measures of output are made with different gauged tubes, thus allowing a diagram to be plotted showing the linear variation of output with variation of pressure.

The remarkable results of the Castelnuovo well (though not so brilliant as those which have since been obtained at Larderello, as recorded above), besides similar ones at other works, were responsible for the experiment of a small, direct feed, free exhaust turbine which was installed at the Serrazzano works and ran in the most satisfactory manner for more than a year. A further experiment was carried out at Castelnuovo in 1925 with a 650-kw. turbine, which has since been followed by two other 750-kw. units. The Castelnuovo plant is ideally simple, the impulse type turbines being fed directly with the *soffioni* steam: the steam enters the turbine at 2 atm. and free exhaust pressure is about 0·1 atm. All expensive and complicated condensing apparatus, with attendant paraphernalia of pumps, cooling towers, etc., are entirely done away with and exhaust steam is sent on to the chemical department for heating concentrating apparatus dealing with boric waters. During its progress from the turbines to the concentrators, the steam is 'washed,' that is, it is made to give up part of the boric acid which it carries. This operation is performed very simply by allowing a jet of water to enter the pipes conveying the steam, by means of an injector device; the water dissolves part of the boric acid and is extracted farther down along the piping. This operation, though not always performed in the case of steam used for power generation, is very extensively resorted to in other instances at the Larderello works and provides part of the boric waters used in the chemical department, the remainder being obtained from the soil where natural jets of steam partially condense.

The new Castelnuovo power station, in comparison with the Larderello plant, has a higher steam consumption per kilowatt-hour, but, on the other hand, cost of plant and expenses of running and upkeep are far lower. Each system has its advantages and, where considerations of expense are of paramount importance, while natural steam is abundant, the free exhaust system appears to be preferable.

At the present moment the total output of power generated by means of natural steam at the Tuscan Boracic Works is more than 6500 kw., with the three power stations of Larderello, Castelnuovo, and Lago, the latter being only a small experimental plant generating about 200 kw. New plants are being studied, and it is confidently expected to attain a total power of at least 10,000 kw. The Società Boracifera di Larderello, which owns all the natural steam springs of the district, has eight different works for the extraction of boric acid, at all of which steam is more or less plentiful, and drillings are being actively carried on in most of these works.

Since the first publication, in 1918, of the results obtained by Prince Ginori Conti, other schemes of the same nature have been proposed in different parts of the world, notable among which is that for utilising the important steam springs of Sonoma County in California, commonly, but improperly, called 'geysers.' According to the reports published, the outputs of steam obtained there by drilling are quite notable, but, so far at least, no machinery of any importance has been installed. Other experiments are reported to be in progress in Java.

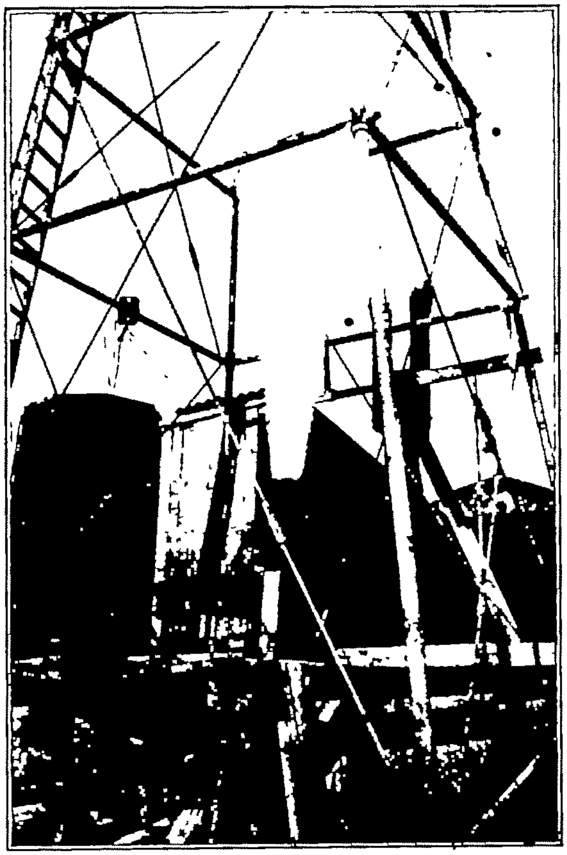

FIG. 3.—A powerful well at Larderello. This well gives more than 60,000 kgm. of steam per hour at 2 atm. efficiency. The steam is seen issuing from a gauged conical tube used for measuring the output of steam.

The Larderello plant is, however, the only concern in the world which is actually working and supplying power derived from natural heat. Larderello is distributing power to the region surrounding the works and is also running in parallel with the important hydroelectric stations which feed the main distribution lines of the western part of Tuscany.

Another striking feature of the Larderello geothermal plant is the utilisation of natural steam not only with regard to its heat contents but also on account of its chemical components. Power is, in fact, an intermediate product, boric acid and its derivates, carbonate of ammonia and carbon dioxide being the final products. From this point of view also, it is undeniable that the methods applied at Larderello constitute the first successful attempt at a complete and rational utilisation of the volcanic or pseudo-volcanic phenomena through which subterranean heat is brought within reach of human efforts.

Parallel Evolution among Protophyta.[1]

By Prof. F. E. FRITSCH.

THE present-day freshwater Algæ represent the most elementary types of holophytic plant-life to which we have access. The probability that such forms will ever be found preserved in the fossil state in sufficient numbers and showing the necessary details of cell-structure to be of any value for comparative morphological study or for the elucidation of the mode of origin of the multicellular plant, appears at the best to be remote.

The relation of the different types of construction that can be distinguished among the lower Protophyta to one another, and to the more elaborate parenchymatous soma usual in land-plants, must always remain in part a matter of conjecture. There are, however, certain definite facts which emerge from a comparative study of the simpler holophytic organisms and that have an important bearing on these problems.

It is now nearly thirty years since the doctrine of the flagellate origin of the Algæ became firmly established by the discovery in Sweden of Chloramœba and Chlorosaccus. These two simple forms agreed with a number of others in the possession of yellow-green chloroplasts containing an excess of xanthophyll and devoid of pyrenoids, the storage of oil, and the possession of a motor apparatus consisting of two very unequal cilia attached at the front end. These and other minor characteristics served to separate out from the extensive group of the Chlorophyceæ a small set of Algæ which became known by Luther's name, Heterokontæ (yellow-green Algæ). The remainder of the Chlorophyceæ were renamed Isokontæ, a designation based upon the fact that here the motile stages bear equal cilia (commonly 2 or 4). In the Isokontæ the chloroplasts are often large and few in number and are commonly provided with pyrenoids; they contain the same pigments as those of the higher plants and, so far as we know, in roughly the same proportions. Most Isokontæ, moreover, store starch.

Already at the end of last century practically every conceivable type of simple plant-body was known in the Green Algæ, ranging from the motile or motionless unicell, through manifold colonial forms, to a more or less highly elaborated filament. This extremely varied somatic development corresponds to a remarkable range of habitat and goes hand in hand with a great diversity in reproductive processes. There is in fact no other group of simple organisms showing such a wide scope in all these respects. By contrast the Heterokontæ, when first distinguished, included only relatively few forms. By degrees, however, many additional members have been discovered, and in the course of this century it has become increasingly apparent that there exists a far-going parallelism between these two classes, Isokontæ and Heterokontæ, which are so sharply segregated by their metabolism and other features that the vast majority of algal workers have regarded them as quite separate evolutionary lines, in no way related to one another.

The Heterokontæ do not, however, exhibit anything approaching the multiplicity of forms that are seen among the Isokontæ; in particular they do not appear to have evolved the motile colony. The less vigorous development accords with the fact that only a few of the more specialised members of the class exhibit sexual reproduction and that this has not passed beyond the phase of isogamy.

The ciliated members of Heterokontæ without exception show 'flagellate' characteristics; that is to say, they are devoid of a cell-wall, their plasma-membrane (periplast) is more or less rigid but usually admits of some change of shape, multiplication is effected by longitudinal division, the protoplast readily encysts, and sexual reproduction is not known to occur. Some of the palmelloid members (*e.g.* Chlorosaccus), possibly all, also show these features. The many motile and palmelloid types among the Isokontæ are, on the other hand, for the most part on a higher plane of organisation and reproduction, being true Algæ provided with a firm cell-wall and usually exhibiting sexuality. When, however, the parallelism between the two classes is recognised, the distinction between flagellate and algal organisation loses force, and it is realised that the assumption of 'algal' characteristics has taken place at an earlier stage in the evolution of the one and at a later stage in that of the other.

These conclusions, however, do not apply only to Isokontæ and Heterokontæ. It is now clear that, in *all* the classes of pigmented Protophyta, an analogous evolutionary sequence has been followed, but that the features associated with what may be called 'algal organisation' have appeared, if at all, at different points in the sequence in the diverse classes. It is no longer feasible to separate the Algæ from the holophytic Flagellata as distinct groups of Protophyta. There is reason to believe that every series of holophytic Flagellates could potentially have acquired algal characteristics, although on the present evidence some have failed to do so.

---

[1] From the presidential address to Section K (Botany) on "Some Aspects of the present-day Investigation of Protophyta," delivered on Sept. 1 at the Leeds meeting of the British Association.

These points are well illustrated by a consideration of Pascher's Chrysophyceæ which, until relatively recent times, were only known to include a wealth of flagellate types, the Chrysomonadales, represented by motile unicells (*e.g.* Chromulina, Ochromonas), by motile colonies (Synura, Uroglena, etc.), and by numerous epiphytic forms. The palmelloid type is also well represented, reaching an exceptionally high differentiation in Hydrurus. But within the last dozen years a quite considerable number of algal members of this class have been discovered on the Continent (for example, Chrysosphæra, Thallochrysis), and it is clear that the Chrysomonadales too have progressed in the same direction as Isokontæ and Heterokontæ, but that here the bulk of the forms have remained flagellate and the minority have become algal.

Another striking instance may be mentioned. The Peridinieæ (Dinoflagellata) are a very distinct and rather specialised class of motile forms, abundant in freshwater and marine plankton. Their most striking characteristic lies in the division of the body of the cell into two usually slightly unequal halves by a transverse furrow harbouring one cilium, whilst the other trails out behind into the water.

In 1912, Klebs described a number of forms that were clearly algal members of this class. His Hypnodinium shows the derivation clearly; it consists of large motionless spherical cells provided with a firm membrane and possessed of the chromatophores and nuclei characteristic of the class. When reproduction takes place, the protoplast contracts somewhat and develops the distinctive furrows, but this is followed by division without resort to a motile phase.

As an antithesis to classes like the Chrysophyceæ and Peridinieæ we have the Myxophyceæ (Cyanophyceæ), where motile types are altogether unknown and all the forms exhibit an algal organisation. Even in this very sharply circumscribed class a considerable degree of parallel with those previously considered can be recognised. Other distinct classes of Protophyta exhibiting holophytic nutrition, but of more restricted range and generally showing special development in one direction or another, are the Bacillariales (Diatoms), the Cryptophyceæ (including the flagellate Cryptomonadineæ and a few little-known algal types), the Chloromonadineæ, and the Eugleninеæ. In all of these, one or other organism can be recognised as parallel with types in the classes that have been previously discussed, although none has evolved the branched filamentous habit so far as at present known. It seems clear that in all the nine classes mentioned evolution has progressed along similar lines and in many cases has led to the production of analogous forms of plant-body.

Amongst the numerous filamentous Isokontæ it is possible to distinguish four separate series, of which the Oedogoniales and Conjugatæ are specialised along directions of their own. Of the other two, the Ulotrichales are the simpler and the Chætophorales the more complex, both possibly originating from a common stock. Many authorities, in fact, fail to distinguish these two groups, but the organisation of the Chætophorales is so distinct from that of the Ulotrichales that, from the viewpoint of comparative morphology, their separation is desirable. Whereas in the Ulotrichales we have a simple or branched filament attached by a more or less elaborate basal cell, the central types among Chætophorales are distinguished, by the possession of a plant-body showing differentiation into a prostrate system of creeping threads, serving *inter alia* for attachment to the substratum, and a projecting system which is more or less richly branched.

This type of construction is not encountered in any of the other nine classes of Protophyta previously mentioned. An analogous differentiation of the filamentous thallus into a creeping and a projecting system is, however, characteristic of many Ectocarpales (*e.g.* Ectocarpus) and Nemalionales (for example, Chantransia), which include the simplest known members of the Phæophyceæ and Rhodophyceæ respectively. In fact, it appears that this kind of plant-body represents a definite stage in the evolution of various classes of Protophyta, affording another instance of parallelism. But, whereas in the Isokontæ it represents the most advanced type of which we have any knowledge, in the two great marine groups it is seen in the simplest of the present-day forms, since no unicellular or palmelloid members of these classes are certainly known to exist.

Of all the holophytic Protophyta, the Phæophyceæ and Rhodophyceæ have alone attained to a high degree of morphological and anatomical specialisation, often affording in one feature or another marked instances of parallel with those groups of the vegetable kingdom which are now dominant on the land. The totally differing metabolism obviously renders impossible, however, any direct derivation of the land-flora from forms belonging to either class.

It will be generally agreed that we must seek the origin of terrestrial plants in organisms possessing the same plastid-pigments and the same essential metabolism as they do. The only representatives of such forms among Protophyta at the present day are afforded by the numerous Green Algæ, the Isokontae. These, however, as has previously been pointed out, stop short at a level of morphological differentiation of the thallus at which the two marine groups commence. Roughly speaking, too, the stature of the most highly differentiated Isokontæ is approximately equivalent to that of the simpler Brown and Red Algæ.

In the Isokontæ we thus have a class of great morphological diversity in which almost every conceivable type of simple plant-body has been realised and is still existent at the present day, but which stops short at a massive parenchymatous construction and forms of large stature. In the

Brown and Red Algæ, on the other hand, where no simple forms of plant-body are certainly known, plants of large size and possessed of a highly developed parenchymatous soma are abundantly represented. It appears improbable that a class like the Isokontæ, showing such extreme capacity for morphological elaboration in every direction and for adaptation to very diverse habitats, should have failed to develop further in the direction generally indicated by Phæophyceæ and Rhodophyceæ. Moreover, it must be remembered that they possess the photosynthetic equipment which has evidently proved to be the only successful one on the land, and that practically every group and family of Isokontæ has its terrestrial representatives.

What then, it may be asked, has become of the more highly elaborated members of this class? It seems to me that there is every reason to suppose that, approximately at the level of morphological differentiation and stature reached by the Isokontæ of the present day, the terrestrial habit was adopted in the remote past, that the more highly elaborated Green Alga became a land-plant, the early forms of which are perhaps yet to be disclosed by palæontological research. In this connexion it is not without significance that the oogamous members of this class for the most part occupy a peculiarly isolated position, appearing as outliers well in advance of the rest, although for none of them is there, to my thinking, any possible connexion with the higher land-plants.

If one recognises among Phæophyceæ and Rhodophyceæ many features of anatomy, life-history, etc., that recall the characteristics of land-plants, I can see in that only a confirmation of the belief that environment has little to do with the broad evolution of the plant-organism, and that these features are a natural outcome of the evolutionary trend in the vegetable kingdom and no positive evidence for the view that they must necessarily have originated in a marine environment. The comparative study of the simpler forms of plant-body in the different classes of Protophyta lends great support to such a concept of a general evolutionary trend.

Obituary.

Prof. Bertram B. Boltwood.

THE tragic death on Aug. 14, 1927, of Bertram B. Boltwood, professor of radiochemistry in Yale University, removes an outstanding scientific personality who played an important part in the rapid expansion of our knowledge of radioactive transformations in the early days of radioactivity.

Prof. Boltwood was born on July 27, 1870, in Amherst, Mass. His father, a graduate of Yale, was of English descent, and his mother of Dutch extraction. He entered the Sheffield Scientific School of Yale in 1889, taking chemistry as his chief subject. After graduation he spent two years at the University of Munich under Prof. Krüss, paying special attention to analytical methods and to the rare earths. The knowledge and technique thus gained was to prove of great importance in his subsequent researches in radioactive minerals. In 1894 he returned to Yale as an assistant in the chemistry department, and did some research work both in organic and inorganic chemistry. In 1900 he left the University to take up work as a consulting chemist, but continued research in his private laboratory.

It was during this period that Boltwood became interested in the study of uranium minerals and the possible genetic relations between the radioactive elements. In 1903, Rutherford and Soddy had put forward the disintegration theory of the radioactive elements and had indicated that radium might prove to be a transformation product of uranium. If this were the case, radium should grow from uranium, and the amount of radium in old unaltered minerals should be proportional to their content of uranium. It was to this latter problem Boltwood first devoted himself in 1904. This involved a systematic chemical analysis of minerals for their uranium and radium content. The amount of radium with the uranium in solution was determined by boiling off the emanation and introducing it into an electroscope. This method in Boltwood's hands became a weapon of precision, and he was able to show that in properly selected minerals the amount of radium was always proportional to the amount of uranium, thus proving that a genetic relation existed between them. If uranium were transformed directly into radium, a solution of uranium, initially freed from radium, should grow radium at a rate that could easily be measured in a few days or weeks. He found, however, no trace of the growth of radium in a carefully purified solution of uranium over a period of about one year, and concluded that an intermediate product must exist between uranium and radium. We now know, due to the work of Soddy, that radium ultimately does appear in uranium solutions, the growth depending on the square of the time; but the small amount of radium produced in the first year is difficult to detect even by the delicate emanation method.

Investigations were then made to see if it were possible to isolate chemically from a uranium mineral the intermediate substance which is transformed directly into radium. A radioactive body was separated which Boltwood found grew radium at a rapid rate. From the similarity of the chemical properties of this body with those ascribed at that time to actinium, he naturally concluded that actinium was the direct parent of radium. Later investigations, however, showed that the properties of actinium had been wrongly described, and that the parent of radium was not actinium at all, but a new radioactive element which he named 'ionium.' In these experiments some thorium was added to the uranium mineral to effect a complete separation of the ionium. Boltwood found that it was impossible by chemical methods to separate the added thorium from the ionium. This was one of the first cases observed of inseparable elements, of which a number of examples came to light in later years. It was on observations of this character that Soddy later put forward the conception of isotopes which has proved to be of so much significance not only for the radioactive but also for the ordinary elements.

By comparing the rate of growth of radium in the separated ionium with the amount of radium in equilibrium with uranium in the mineral, Boltwood was able for the first time to fix by a direct method the average life of the radium atom. In later researches he was able to show that a genetic relation also existed between actinium and uranium, but that the amount of actinium was only a few per cent of that to be expected if it were in the main line of descent. This work suggested that the actinium must be regarded as a branch product at some point of the uranium-radium series. This is a conclusion we hold to-day, but the exact point of branching is still uncertain.

These investigations, which were carried out with great experimental skill and accuracy, thus yielded results of fundamental importance. Boltwood had not only proved a genetic relation between uranium and radium, but also had isolated the new element which was the immediate parent of radium, and had shown that actinium was also genetically connected with uranium but not in the main line of descent.

I must not omit here to refer to another deduction which has proved to be of great importance. As a result of his own analyses and the analyses of Hillebrand, Boltwood found strong evidence that the amount of lead in old minerals of the same geological age is proportional to their content of uranium and increases with the geologic age. This led him early (1905) to suggest that lead was the final inactive product of the uranium-radium series of transformations. The correctness of this view has been abundantly verified in recent years. We know that the end product of uranium is an isotope of lead of atomic weight 206, and the end product of the thorium series is another isotope of weight 208. These observations have thus supplied a definite method of estimating the age of radioactive minerals and thus of the geological horizons in which they are found.

The importance of Boltwood's work was at once recognised by Yale University, where he was appointed assistant professor of physics in 1906 and professor of radiochemistry in 1910. He took an active part with the late Prof. Bumstead in building the new Physics Laboratory in Yale, and later, in 1918, as professor of chemistry, in building the new chemical laboratories. The labour and detail involved in such undertakings, which he cheerfully undertook, made serious inroads not only on his time for research but also on his energy. He had a breakdown in 1922, and never completely recovered from its effects.

I first made the acquaintance of Boltwood in 1904, when he was carrying out his first radioactive experiments. One could not fail to be impressed by the breadth and accuracy of his scientific knowledge, and by his scrupulous care and accuracy in experimental work. He possessed to an unusual degree the power of anticipating experimental difficulties which were likely to arise and in arranging his apparatus and methods to overcome them. This characteristic feature of Boltwood's work was well illustrated in his investigations with me in the University of Manchester in 1910 on the rate of production of helium by radium and other radioactive bodies. Every detail of the complicated apparatus and arrangements was so carefully thought out beforehand that not a single change was required for the successful conclusion of the measurements.

A man of cosmopolitan tastes, Boltwood was much attracted by many aspects of European life and spent many of his summers on the Continent. He took an active interest in the undergraduate life of his university and had the gift of gaining the interest and confidence of young people. His premature death will be mourned by a wide circle of friends, who held him in high esteem for his personal qualities as well as for his outstanding scientific achievements.

E. RUTHERFORD.

MR. W. H. DINES, F.R.S.

BY the death of Mr. William Henry Dines, meteorology loses an outstanding figure. It is scarcely possible to overrate the importance of his work. He was a meteorologist of the first rank before he began the upper air work for which he is best remembered. Born in 1855, he was the son of George Dines, himself a meteorologist of note. He was educated at Woodcote House School, served an apprenticeship as a railway engineer, and then went to Christ's College, Cambridge; he obtained first class honours in the Mathematical Tripos, and took his B.A. degree in 1881. The bent of his first meteorological work was occasioned by the disaster to the Tay Bridge, which, only recently opened, was destroyed by a gale while a train was crossing it. So George Dines investigated wind pressure and his son helped him. Later, as a result of this work, W. H. Dines designed the pressure tube anemometer. This instrument in its final form records each gust of wind and each transient change of direction, and is the standard recording anemometer for all serious purposes.

Dines's most notable work, that of upper air research, began in 1901 with kite ascents. When possible, Dines always preferred to design and make his own apparatus, and it was his modification of the box kite, his winding gear, and his meteorographs which were used. The meteorograph was simple, efficient, and cheap, a great point for upper air research, when instruments are apt to be lost or broken. Dines took observations at Crinan, on the west coast of Scotland, in the summers of 1902 and 1904, flying kites from a shore station, from a tug in 1902, and from H.M.S. *Seahorse*, lent by the Admiralty for the purpose in 1904. He also used his house at Oxshot in Surrey, and later at Pyrton Hill, near Watlington, as an upper air observatory.

As the investigation progressed, greater heights were required than could be attained by kites, and Dines used sounding balloons. His balloon meteorograph with its metal case weighed only two ounces, and cost only about one-twentieth of the price of instruments used on the Continent and in the United States. Being so light it allowed much smaller balloons to be used. The whole cost and difficulty of sounding balloons were so much reduced that the Department of Physics at the University of Manchester was able on two occasions to send up a balloon every hour for twenty-four hours. He designed also a very ingenious apparatus for calibrating the meteorographs. Accounts of these and many other instruments, and many papers on meteorology, especially on wind pressure, upper air research, and, later, on radiation, are to be found in the publications of the Royal Society, the Royal Meteorological Society, the Meteorological Office, and elsewhere.

Dines had a wonderful insight as to what was necessary in an instrument. He could design it, make it himself in many cases, use it to the best advantage, and afterwards discuss the results obtained. It was the possession of these qualities, seldom all united in one person, that marks the genius that he applied to meteorology. It was as an amateur that he worked. Most sciences have been started by amateurs, but by degrees they have grown out of the stage when an amateur can usefully apply himself to their problems. Meteorology has possibly reached this stage. Dines was the last and the greatest of the amateurs who built up the science, and he has left it in a very different condition from that in which he found it. Now it is recognised as a real science worthy of study by mathematicians and physicists of the first rank. He had a great share in bringing it to this stage.

Most of the sounding balloon work was done by Dines at Benson, near Wallingford, where he went from Pyrton Hill. It was chosen as being in a part of England most favourable for balloon ascents. Dines himself hoped that Benson would become ultimately a permanent aerological observatory, and indeed at one time this was to have been its destiny. Fate, however, intervened, and to the regret of many the dream will not come true.

Dines joined the Royal Meteorological Society in 1881; he was for a number of years a member of council; he was president in 1901 and 1902; and in 1914 he received the Symons Gold Medal of the Society. In 1905 he was elected a fellow of the Royal Society. From 1905 until 1922 he was Director of Experiments on the Upper Air for the Meteorological Office, and a small annual grant was made for the maintenance of the establishment, first at Pyrton Hill, afterwards at Benson; but Dines received no personal emolument; so far as his own services went, his position was an honorary one. Perhaps because he was never in the employment of any Government office, or the holder of any public post, perhaps because he was of a very modest and retiring nature, and would never have dreamt of pushing himself into public notice, he received no public honour of any kind. Probably in no country but Great Britain would such eminence in a science which has become of such great practical importance have passed unrecognised.

Dines was a real student, wrapped up in his work, and in the subject he had made his own. He was singularly retiring, and had the constitutional shyness which not seldom goes with genius. But those who penetrated his reserve found that he could have, and maintain, strong opinions, and that he had a quiet but very real sense of humour. He was ever ready to help others who were working on the same lines as his own, and took infinite pains in this way, as the writer can testify from the experience of many years. He is survived by a widow, and by two sons who carry on the family tradition of meteorology into the third generation, for they both have posts in the Meteorological Office.

The early years of the century will stand out by reason of great advances made in many sciences, especially in physics and astronomy. Meteorology advanced rapidly at the same time, and in Great Britain it was Dines who led the way. Physics and astronomy are still in the period of rapid advance. Meteorology shows signs of decreasing acceleration. Can we look forward to a further advance, which only research can ensure? Given the will, it is possible; but we shall not so easily find again the genius of a Dines.

C. J. P. CAVE.

DR. HERMANN KAST, well known for his work on explosives, died on Sept. 6, 1927, aged fifty-eight years. After a period of study in A. W. Hofmann's laboratory in Berlin, Kast graduated in 1893. For many years he was a member of the council and deputy-president of the Berlin Bezirksverein deutscher Chemiker. In addition to numerous original scientific publications, Kast published two comprehensive works dealing with explosive materials.

WE regret to announce the following deaths:

General Henry L. Abbot, the distinguished U.S. Army engineer, who was elected a member of the National Academy of Sciences in 1872, on Oct. 2, aged ninety-five years.

Mr. Leon Gaster, honorary secretary of the Illuminating Engineers' Society, on Jan. 7, aged fifty-five years.

Prof. H. W. Mackintosh, formerly professor of zoology and comparative zoology in the University of Dublin, a post which he held for nearly fifty years, on Jan. 8.

Dr. Frederick C. Newcombe, emeritus professor of botany in the University of Michigan, and secretary in 1897 of Section G of the American Association for the Advancement of Science, who worked particularly on the sensitive reactions of plants, on Oct. 1, aged sixty-nine years.

Dr. Geo. A. Osborne, emeritus professor of mathematics at the Massachusetts Institute of Technology, on Nov. 20, aged eighty-eight years.

Prof. F. W. Very, director of the Westwood Astrophysical Observatory at Westwood, Mass., since 1906, on Nov. 23, aged seventy-five years.

News and Views.

TUESDAY last, Jan. 10, marked the one hundred and fiftieth anniversary of the death of Linnæus. Carolus Linnæus—afterwards Carl von Linné—was born on May 23, 1707, the eldest child of Nils Linnæus, pastor of South Råshult, in the south of Sweden. After a schooling that lasted until he was twenty years old, Linnæus spent one year at the University of Lund and five years at the University of Upsala, the latter period interrupted by his famous five months exploration of Swedish Lapland in the summer of 1732. Then followed a fruitful three years' sojourn abroad—mostly in Holland, but with visits to England and France—succeeded by three years as a physician in Stockholm. Finally, he was appointed in 1741 to the chair of natural history in Upsala, a post which he held until his death.

IF we make in modern fashion a fanciful aeroplane survey of the rich, varied, vast, and ever-broadening territory occupied by the biological sciences during the last one hundred and fifty years, it is easy to lose sight of the small tract of thorny wilderness out of which they were trying to struggle before the coming of Linnæus. Before him there were pioneers like Bauhin, Gesner, Ray, and Tournefort, who had attempted to clear a track to the open country, but it was Linnæus who transformed their cumbersome and uncertain direction finders into instruments of precision, who brought the wanderers out of the jungle and laid down a base line for the survey of the promised land beyond. Although Linnæus had but a glimpse of the fair regions which those who have come after him enjoy, and although some of his instruments have been superseded and others refined, his base line still remains. All collective knowledge depends on the correct and accepted use of names, and the incomparable service rendered by Linnæus in his "Species Plantarum," "Systema Naturæ," and other works, was to establish, in the study of all things that live or have lived, an accurate and universally accepted system of nomenclature. To amplify the expression of one of the greatest of living zoologists, Linnæus was the Adam of the biological sciences. So all who labour to increase man's knowledge of himself and all other creatures, great and small, do well to hold his name in honourable remembrance.

METEOROLOGICAL conditions, and especially the swollen state of the upper Thames resulting from the melting of snow, had doubtless a good deal to do with the recent abnormal tides and floods which caused loss of life and much distress in Westminster and low-lying parts of London. There were also astronomical factors to reinforce the effects of the gale and the swollen river. The night tides at winter full moons are helped by the north declination of the moon at such times. On Saturday morning, Jan. 7, the moon's north declination was 25°, so that it was only 26½° from the zenith in London, and the sun was only 28° from the nadir. Also the sun was near the earth, having passed perihelion on Jan. 4. The moon was in perigee late on Jan. 3, and was still considerably nearer the earth than its average distance. The night tides at full moon are higher than the day tides, the moon being nearer in the former case by nearly the diameter of the earth. The day tide at midsummer new moon is also high, but less so than the midwinter night tide, owing to the greater distance of the sun. The conditions on Jan. 7, when the floods occurred, were not the most favourable possible, the moon being more than three days from perigee, but they were much above the average. The actual conditions are less simple than those sketched here, the British tides depending on the conditions in the ocean at some distance away, rather than on the direct action of the moon on the narrow seas round Great Britain. It is for this reason that the highest spring tides do not generally come until one and a half days after new and full moon. But on Jan. 7 the highest tide appears to have come on the actual night of full moon; this must have been due to the prevailing meteorological conditions, which piled up the water in the North Sea and prevented the flow out of the river, rather than to astronomical causes. The tide is said to have reached the highest point ever known in the Thames.

THE Egyptian Minister of Education has just issued invitations for the celebration next December of the centenary of the Faculty of Medicine in Cairo, which is to take the form of an International Congress of Tropical Medicine and Hygiene under the patronage of the King of Egypt. The chequered history of the Cairo School of Medicine presents a number of incidents that suggest romantic stories from the Arabian Nights rather than sober history. From the time of the famous Alexandrian School of Herophilus and Erasistratus, which created the systematic study of anatomy, there was nothing worthy of the name of a medical school in Egypt until a century ago. The story goes that one afternoon the Viceroy, Mohammed Ali, was driving through the streets of Cairo on the way to the Shubra Palace when he ordered his coachman to stop and, summoning a well-dressed Frenchman who was walking along the street, informed the stranger that he wanted him to create a medical school in Cairo! When the latter protested that he was a wine merchant and not a medical man, the Viceroy refused to listen to his excuses and insisted on his orders being carried out.

CLOT BEY, in spite of his ignorance of medicine, was an able man, who accomplished the task thus entrusted to him with conspicuous success, which was recognised later by the conferring of the M.D. degree on him by the University of Paris. Napoleon I. had founded a military hospital in Cairo, and around the civil hospital which afterwards replaced it, and later was transferred to Kasr el Ainy, the medical school was built up. Among the able staff which Clot enlisted was the anatomist Bilharz, whose discoveries in helminthology have made his name familiar to every student of medicine. Thirty years ago the late Lord Cromer recommended the reformation of the School, which had become moribund. Acting on the advice of Sir Cooper Perry, the school and hospital were in large measure restaffed and developed in accordance with British ideas, so that they became important instruments of medical education and research. With the granting of Egyptian independence, the medical school passed under the control of the new Egyptian university. The Congress marking the centenary of the school should be one of exceptional interest.

IT is unlikely that the attempts which are being made in the French press to discredit the findings of the International Commission on Glozel will carry any weight with those who are competent to form a judgment on the evidence. If, however, there should be any who still, after the publication of the Report, find a difficulty in forming an opinion, they should be convinced by Sir Arthur Evans's letter in the *Times* of Jan. 7. Not only does he fully endorse the findings of the Commission, but he also thinks they might have found stronger expression. He points out that beyond the material findings to which the Commission has confined itself, there are certain considerations which should be borne in mind. "To accept as genuine," he says, "the accounts of these discoveries would be to destroy the whole fabric of our knowledge of the successive stages of the earlier and later Stone Ages." He goes on to point out how the immediate juxtaposition of the Magdalenian period and Glozel, itself dated no earlier than the end of the neolithic period at Knossos, runs counter to our knowledge of the stages later than the Magdalenian and ignores the high antiquity of the neolithic period, the stratified deposits of which at Knossos lie in places to a depth of 36 feet below the earliest Minoan, itself extending well into the third millennium B.C. Sir Arthur's pronouncement on the finds themselves, which he has now examined personally, will be welcomed by archæologists. In his opinion they are one and all the work of the same industrious hand, and "it is difficult to understand how they can deceive any expert eye." They present the most startling incongruities; the culture is of all ages, while the script contains selections from historic alphabets. The tiles of the glass furnace supplied the models for the bricks, its crucibles for the 'mud-pie' pots, and the inscriptions were derived from the collections or publications of M. Perot of Moulins, a local antiquary.

AT the annual meeting of the Geographical Association, held on Jan. 4-7 at the London School of Economics, Dr. Marion I. Newbigin delivered a lecture directing attention to the need for a new approach in geography teaching. Too much emphasis has been laid, she said, on the logical sequence beginning with climate and leading on to a study of vegetation and human activities. Arithmetically determined 'means' are of little use for children and do not lead to an appreciation of actual climatic conditions. The study of house types should take the place of climatology, which is too prominent a feature of geography teaching. Of supreme importance is the organic response to normal and usual conditions and the degree of tolerance of the abnormal. Sir John Russell, in discussing the agricultural problems of Palestine, showed the necessity for afforestation in that country. The run-off from the arid Jordan slopes of the Judean Highlands is so rapid after torrential rains that the soil is washed away. If trees were to be planted, their roots would hold up the water and springs would issue from the hillside. This water could be regulated and utilised for irrigating fruit gardens in the valley below. Mount Carmel should be re-afforested for the benefit of the Plain of Esdraelon, the swamps of which are being converted into irrigable land. Stock-raising difficulties are the result of the spread of diseases by the flocks and herds of Bedouin nomads. These animals are also responsible for serious depredations among newly planted cypress and fig saplings in the recently afforested areas between Jerusalem and Jericho.

PROF. RODWELL JONES, speaking at the annual meeting of the Geographical Association on the economic development of the Prairie Provinces of Canada, stressed the importance of irrigation in Western Alberta, where the climate favours the growth of hard wheat with a high gluten content. No storage works are necessary in the mountain zone, since the maximum flow of the rivers coincides with the opening of a short growing season. Nevertheless, irrigation is too expensive for general adoption. Vancouver is the main outlet for the region, although the completion of the Hudson Bay Railway to Fort Churchill, not Fort Nelson, is to be hastened. The coal reserves on the Prairie, though easy to extract, are of an inferior quality with a high ash and water content; they crumble on prolonged exposure and have a low calorific value. High-grade coal of the mountain region is difficult to mine. Sir E. Humphrey Leggatt, who delivered a lecture on "Economics and Administration in British East Africa," spoke of the Commission about to visit East Africa to consider possibilities of greater unification in the government of the area. He referred to the growing public demand for news relating to East Africa, especially that concerned with morals. He questioned the advisability of delimiting native reserves, and spoke in high terms of the system of interpenetration adopted in Uganda and Tanganyika Territory. This scheme recognises native rights to the land, and only very small blocks are alienated to Europeans. The total available native labour is inadequate for the vast European estates in Kenya, and further immigration of Europeans, together with additional alienation of land, is not for the good of the colony. It is important to avoid the development of a 'poor white' class as in South Africa.

A STATEMENT by Sir John Marshall that a monograph on the important excavations in the Indus Valley will appear in the coming summer is welcome news to archæologists. They have long awaited the opportunity for careful consideration of the finds on the two sites of Mohenjo-daro and Harappa which will be afforded by the fuller publication of results now promised. In the meantime, Sir John Marshall, in the *Times* of Jan. 4 and 5, has given some account of the more recently obtained material, and has surveyed the general conclusions to which he has been led by maturer consideration. Of these, perhaps the most important is the view that the early culture which has been revealed here should not be regarded as Indo-Sumerian but should be known as 'Indus' culture, on the ground that there is not so much identity of culture in Sumeria and Northern India as a close connexion due to commercial or other intercourse. As regards dating, Sir John Marshall suggests that the Indian seals found at Susa and elsewhere in Mesopotamia, belonging to the time of Sargon I. of Akkad (2700 B.C.) or before, would give a date of about 3300 B.C. for the first of the three latest cities at Mohenjo-daro, the uppermost cities at Harappa being about contemporary. This would give a very early date for the lower cities with the primitive seals and other antiquities on the latter site.

So far as evidence has been obtained, the inhabitants of Mohenjo-daro were of the dolichocephalic type, with the exception of one brachycephalic skull from a burial. But although they all belong to the chalcolithic period, they were long after the destruction of the latest city. One of the most interesting objects found at Harappa was a model in copper of a two-wheeled cart which, if the dating is correct, would long antedate the representation of a wheeled vehicle recently found at Ur, which in turn antedates the use of the wheel in Egypt by a thousand years. It is also noteworthy that the drainage system and other features suggest a higher standard of amenity than is found at Ur. In certain 'standard'-like objects, Sir John Marshall sees the possibility of a connexion with Egypt.

THE fifth annual meeting of British zoologists was held on Jan. 7, at the rooms of the Zoological Society, ninety-four zoologists attending, and three guests. Owing to illness of the chairman-elect, Prof. W. Garstang, the chair was taken by the vice-chairman, Dr. G. P. Bidder. Prof. Douglas Laurie and Prof. E. W. MacBride introduced the Report of the Committee appointed to consider the question of animal biology in the school curriculum. All present expressed their conviction that the teaching of animal biology in schools is an urgent necessity. Subject to certain suggestions for the further consideration of the Committee, the Report was adopted unanimously, and the Committee empowered to act for the meeting in making the contents of the Report known and in co-operating with other bodies interested in the subject. For the discussion on "The Scale of Pay of Zoologists," the honorary secretary, Prof. F. Balfour Browne, produced a file of returns of salaries to zoologists at various universities, etc. Dr. Chalmers Mitchell, Prof. Stanley Gardiner, and the honorary secretary were appointed as Committee to examine the material and report to the next annual meeting. In a discussion which followed, all speakers agreed that it is difficult now to induce good men to apply for posts as zoologists in Government service. Although the zoological civil servant requires two more years of education than an administrative civil servant, yet at the age of thirty-five his salary is inferior by 30-50 per cent. It was unanimously resolved: (1) "That this meeting of British zoologists urge on the Government and on Universities the necessity for proper pay and conditions for zoologists in their service." (2) "That the Committee appointed to deal with the returns of posts and salaries of zoologists be asked to advise and suggest as to the steps to be taken to carry out this resolution, and meantime be empowered to act for the meeting."

THE meeting then discussed the Great Barrier Reef Expedition of 1928. Sir Sidney Harmer proposed: "That, in the opinion of this meeting of British zoologists, the investigation of the Great Barrier Reef of Australia is likely to produce valuable additions to knowledge, by elucidating questions of fundamental importance in relation to the growth of coral reefs, and the general biology of marine animals and plants in the tropics; and that progress in this direction will materially assist in the development of the economic resources of Australia." The motion was seconded by Dr. C. M. Yonge, the leader of the Expedition, and carried unanimously. The meeting was informed of the promised co-operation of the Royal Geographical Society, and that, in addition to financial assistance promised by the Australian Barrier Reef Committee, the British Association, and the Zoological Society; the Marine Biological Association has given permission for Mr. F. S. Russell to initiate the plankton researches. Private donors have promised £600. Dr. E. J. Allen and Dr. W. T. Calman then opened a discussion on the present position of binomial nomenclature, and the resolution "That this meeting of British zoologists is in favour of a substantial extension of the lists of *nomina conservanda*," was carried.

THE question of the closer relationship and a better understanding between sheep-breeders and woollen and worsted manufacturers has recently been under consideration by the British Research Association for the Woollen and Worsted Industries, with the view of placing the former in a position of having more precise and definite details of the requirements of the latter. In the determination of the quality of wool, various considerations arise, for example, fineness, diameter, staple length, crimp, etc.; all these must be fully investigated before the manufacturer's requirements can be standardised and the wool-breeder informed exactly what the manufacturer's specifications are. With the view of accelerating the investigations considered by the British Research Association for the Woollen and Worsted Industries, the Empire Marketing Board has granted a capital sum of £7000 as well as an annual contribution of £2000 to the Association for the specific purpose of the study and investigation of wool 'quality.' In order that the whole range of investigation may be complete, a joint programme of research work has been arranged between the Research Association and the Animal Breeding Research Department, University of Edinburgh, to which the Empire Marketing Board is also contributing an additional grant.

THIS grant in no way affects the ordinary work of the British Research Association for the Woollen and Worsted Industries; it is made for a specific problem to be investigated alongside the research work already in hand. In order to carry out the work, sanction has been given for the purchase of additional premises and the creation of new laboratories for biology, biochemistry, colloidal physics, etc., and for the provision of special staff. For the full benefit of the work entrusted to the Association by the Empire Marketing Board to be obtained, additional support for the general programme of research should be forthcoming from the trade itself. In order to encourage this, the Department of Scientific and Industrial Research has agreed to maintain its grant of £4800 for the current year, instead of reducing it to £1200, as would normally have been done. It now remains for the industries themselves to supplement this generous support (based on a careful examination of the work that is being carried out) by increasing their financial interest in this important and vital section of their organisation.

THE annual meeting of the British Ecological Society was held in the New Botanical Department of the University of Birmingham on Jan. 7. Dr. E. J. Salisbury was elected president, Mr. H. Boyd-Watt, vice-president, and the vacancies on the council were filled by Prof. A. E. Boycott and Dr. V. E. L. Anderson. The honorary treasurer in presenting the balance sheet stated that the Society is now in a better financial position than ever before and a further £200 has been invested. The honorary secretary reported that the council has recommended the preparation of a biological flora of Britain which shall contain such information as is available with regard to biological features of ecological significance. A scheme prepared by Dr. Salisbury was approved, and the recommendation of the council that Dr. Salisbury should act as editor was adopted. Mr. Turrill reported that experiments on growing selected plants in various soils have been started at Pottern under the direction of a sub-committee consisting of Dr. A. W. Hill, Prof. Oliver, Dr. Salisbury, Prof. Tansley, and himself. Papers were communicated by Mr. C. S. Elton on "Animal Communities in the Arctic"; by Mr. W. Leach on "The Vegetation of Screes"; by Miss M. K. Bishop on "The Ecological Relationship between Some Species of Juncus"; by Prof. F. W. Oliver on "Early Stages of a Sand-Dune"; by Dr. V. E. L. Anderson on "The Root-Hair in the Soil"; by Dr. W. H. Pearsall on "Michigan Sand-Dunes," and by Prof. Adamson on "The Vegetation of Eastern Rhodesia."

IT is announced by the Colonial Office that platinum has been discovered in Sierra Leone. It was first found in May 1926 by the Director of the Geological Survey, Major N. R. Junner, and a recent investigation by him indicates that the platinum-bearing area is about forty square miles in extent, and that the deposits, which are alluvial, are likely to be of considerable importance. One nugget of platinum weighing 7·4 gm. (4¾ dwt.) was found by Major Junner. This nugget and some of the smaller grains of platinum have been presented to the British Museum (Natural History), South Kensington. An analysis made by the Imperial Institute of the platinum shows that it compares very favourably in composition with the platinum from the Urals and from South Africa. The platinum in Sierra Leone is associated with basic igneous rocks resembling those of the Bush Veld igneous complex of South Africa in which important deposits of platinum metals have been found.

DR. E. SCHRÖDINGER is to lecture in London on wave mechanics at the invitation of the Royal Institution. It has been arranged provisionally that the lectures shall be given on Mar. 5, 7, 12, and 14 at 5.15 P.M. The lectures will be held at the Royal Institution, and will be open to the public.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A head of the Chemistry and Industrial Chemistry Department of the Technical College, Cardiff—The Principal, Technical College, Cardiff (Jan. 21). An assistant for technical records work at the Building Research Station, Watford—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Jan. 21). A city analyst under the Leeds Corporation—The Town Clerk, 26 Great George Street, Leeds (Jan. 25). An assistant at the Low Temperature Research Station, Cambridge, for abstracting scientific and technical papers on the preservation and transport of foodstuffs—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Jan. 26). A graduate to undertake and direct research work at the Glasgow Royal Cancer Hospital—The Secretary, Glasgow Royal Cancer Hospital, 156 St. Vincent Street, Glasgow (Jan. 31). Temporary assistant chemists at the Government Laboratory—The Government Chemist, Clement's Inn Passage, W.C.2 (Jan. 31). A professor of civil engineering at the Bengal Engineering College, Sibpur, Bengal—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S.W.1 (Feb. 1). A secretary of the Royal Sanitary Institute—The Chairman of Council, Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.1 (Feb. 11). A professor of zoology in the University of Manitoba—The Secretary, Board of Governors, University of Manitoba, Winnipeg, Man., Canada. Test assistants at the Royal Aircraft Establishment for work in connexion with the airworthiness approval of aircraft—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (quoting A. 232). A junior lecturer at the Port Elizabeth Technical College, South Africa, qualified to teach elementary mathematics, science, and trade drawings—Box "Z.D. 797," c/o Deacon's Advertising Agency, Fenchurch Avenue, E.C.3. A junior assistant, with museum training in natural history, at the Hancock Museum, Newcastle-upon-Tyne—The Honorary Secretaries.

Research Items.

ARCHÆOLOGICAL DISCOVERIES BY AEROPLANE AT DORCHESTER.—In *Antiquity* for December, Mr. O. G. S. Crawford describes an interesting series of archæological discoveries near Dorchester, in Oxfordshire, due to photographs taken from the air in June last by two officers of the Royal Air Force, Flight-Lieuts. W. E. Purdin and B. T. Hood. The photographs revealed two large circles previously entirely unknown, a rectangular enclosure having no relation to existing field divisions, a semi-circular enclosure, possibly prehistoric, a track, either prehistoric or Romano-British, forty feet wide—an unusual width—traces of several barrows, and a small circle about twenty feet in diameter, consisting of twelve holes which had once been filled with uprights of stone or wood. The two concentric circles first mentioned, it is interesting to note, were partly in two fields, one under barley, the other under beans; but it was only the bean field that showed the circles, of which no trace was to be seen at all at ground level. In order to test the circles and seek evidence of their date, excavations were carried out by Mr. Crawford and Mr. R. G. Collingwood in October. Two trenches were cut, the first of which found the inner circle. At one end of the trench the excavators came on sand at a depth of 2 ft. 6 in. through a deposit of reddish-yellow loam. At the other end, sand was reached at a depth of no less than 6 ft. 4 in. of brick earth, the silt filling up the old ditch. The circle-ditch originally must have been not less than 36 ft. across from lip to lip. The second trench cut the outer circle at the point where the crops divided. Here a layer of 2½ ft. of brick earth covered the sand, and the sides could be seen sloping away from the inner lip. At a depth of 5 ft. 6 in. a foot of black stuff represented the middle of the ditch. Beyond two animal bones and some fragments of bone, no finds were made. The dig, as well as the examination in detail to which Mr. Crawford has subjected the photographs, is a useful demonstration of the value of air photographs, and has thrown much light on what may be termed the technique of their use in archæological discovery.

GOITRE IN SCHOOL CHILDREN.—In the recent issue of the *Annals of Eugenics*, Dr. Percy Stocks is continuing his valuable studies on the influence of iodine in reducing or preventing the incidence of goitre in school children, and in particular of increasing the rate of growth of school girls in height and weight. In collaboration with Miss Mary Karn, he corroborates for large towns in England and Wales the inferences drawn from Swiss and American statistics, that there is a positive relationship between the prevalence of thyroid enlargement in children and cancer mortality.

ICE-DRIFTS AND SEAL-FISHING.—Dr. Thor Iversen ("Drivis og Selfangst," *Aarsberetning vedk. Norges Fiskerier*, Hefte 1, Bergen, 1927) gives an interesting account of the northern seal fisheries of the ice-drifts with particulars of the biology of the seals and a detailed history of the seal-fishery. The most important seals for the industry are the Greenland or Harp seal *Phoca groenlandica* and the Bladder-nosed seal *Cystophora cristata*, but for the more northern fisheries the walrus *Trichechus rosmarus*, Bearded seal *Erignathus barbatus* and Ringed seal *Phoca fœtida* are of distinct significance. Most of the work refers to the first two species, especially the Greenland seal. Descriptions are given of its breeding places and habits, distribution, and the methods employed in catching it. Both of these seals are truly sea animals and undertake long migrations, keeping in large herds. Their breeding places are the ice-drifts of Jan Mayen, mouth of the White Sea, the Newfoundland ice and the Gulf of St. Lawrence, where the young are born from early February to April. There is a large industry for the young seals, which are left to fend for themselves very early in the case of the Greenland seal and are captured before they are able to swim. The Bladder-nosed seals, both male and female, on the other hand, defend their young, keeping with them for a longer time, and do not fly from the hunters, who shoot down whole families at one time. The questions asked by the writer with regard to the Greenland seal—do the individual seals keep to one breeding-place throughout their life, do all individuals of a group come from a single stock, and, finally, the large question of preservation, are only partially answered and, as he says, much more work is necessary before any answer can be attempted. Researches are needed similar to those already made on the fur seals, which present much less difficulty, breeding as they do in the summer and on land.

A MITE ON A SILKWORM PARASITE.—An interesting account of *Tyroglyphus muscæ*, a mite infesting *Sturmia sericariæ*, a fly noxious to the silkworm, is given by Dr. Chujiro Sasaki (*Journal of the College of Agriculture*, Imperial University of Tokyo, vol. 9, No. 3, Aug. 1927). *Sturmia sericariæ* passes the winter underground as a pupa which is nearly always parasitised by a small mite, *Tyroglyphus muscæ*, a serious pest to the fly. Experiments were undertaken to find out whether the mite attacks the silkworm directly. For this purpose specimens were introduced into vessels containing silkworms in various stages of development, and it was found that the mite invades both pupa and imago, but specially attacks the silkworm at the time of moulting. The silkworm gradually becomes weak and sickly looking and soon dies. The mite attacks various parts of the body of its host, particularly both the thoracic and abdominal legs, which are marked by brownish or blackish patches. Detailed descriptions are given of both the male and female mite and of the life-history, involving four ecdyses with only about twenty-four hours on an average in between the stages. It thrives best in dark and damp places, and can live for two days immersed in water, perishing under dry conditions.

STOMATAL FREQUENCY.—Some interesting facts regarding stomatal distribution in plants from various habitats, but with special reference to woodland forms, have been published by E. J. Salisbury (*Phil. Trans. Roy. Soc.*, Series B, vol. 216, pp. 1-65). Stomatal frequency in the individual leaf shows great variation, being greatest where suction force and osmotic pressure are greatest, although no general relation between stomatal frequency and osmotic pressure is suggested other than a parallel response to the operation of some other factor. Contrary to what traditional interpretations have taught us to expect, Dr. Salisbury finds stomatal frequency to be higher in sun leaves than in shade leaves, and higher in the case of plants grown under xerophytic conditions than in plants from more humid habitats. Comparison between plants grown in dry and moist air respectively indicates that stomatal frequency is mainly dependent on the humidity of the environment. The term 'stomatal index' is used to denote $100 \times S/(E+S)$, where S denotes number of stomata per unit area, and E the number of epidermal cells in the same area. By means of this index it is shown that the *proportion* of stomata found in the epidermis is no greater in sun leaves than in shade leaves, but there is a higher positive correlation coefficient between the number of stomata and the number of epidermal cells per unit area. The differences are all shown to be due to differences in the growth of the epidermal cells, and the consequent difference in spacing of the stomata. It is claimed that with the exercise of proper precautions as to region of leaf examined and with due regard to its variable character, stomatal frequency has an important ecological significance as an indicator of the humidity of the environment.

CATALASE AND PLANT GROWTH.—The change in the growth of plants in passing from the merely vegetative phase to the reproductive phase is accompanied in the tissues concerned by a corresponding change in the type of metabolism. In *Memoir of the Cornell University Agricultural Experiment Station*, No. 106, J. E. Knott gives numerous data to correlate the catalase activity of the apical bud of spinach with this change in metabolism. When the reproductive phase begins, catalase activity decreases, but the effect seems localised in the one tissue and is only slightly evident in the leaves. Correlated with this decrease in catalase activity, there seems to be a drop in the respiratory rate as determined by the evolution of carbon dioxide. Yet it seems as if new tissue were being formed much more rapidly in the flower stalk than in ordinary vegetative growth. One would expect, therefore, a higher rate of respiration to provide the requisite energy. This increased respiration may be present, and yet not of a type resulting in the evolution of carbon dioxide or associated with catalase formation. In some types of tissue, catalase seems to be related to total respiration. Catalase from apple fruit tissue maintains its maximum activity after the material has been removed to conditions less favourable for its production, and the rapid disappearance of spinach catalase is possibly related to a lower degree of stability. The response of catalase to nitrogen and carbohydrates is interesting. Knott finds that calcium nitrate added to catalase *in vitro* decreases, while asparagin, sucrose, and soluble starch increase activity after 24 hours; *in vivo* the effects of those substances are practically the opposite, the explanation of which is a problem still to be solved. A useful modification of the Bailey hydrogen electrode for measuring the hydrogen ion concentration of liquids which froth readily is described.

PULSATIONS OF THE EARTH'S CRUST.—Part 5 of vol. 2 (Section 2) of the *Jour. Fac. Sci. Imp. Univ., Tokyo*, is devoted to an interesting paper by T. Matuzawa on pulsatory motions in the earth's crust. These were noticed long ago by Milne, but though often studied their nature remains uncertain. G. W. Walker suggested that they are due to Rayleigh waves set up at the sea bottom by water waves, caused by wind, at the surface of the sea. In Japan they are sometimes of considerable magnitude, 0·5 mm. or more, and to these the suggested explanation seems inapplicable. The paper describes the pulsations observed in Japan, and concludes that changes of atmospheric pressure play the most important part in their production. It is suggested that the movements are probably elastic vibrations of some oscillating system proper to the locality of origin.

A CLASSIFICATION OF IGNEOUS ROCKS.—A new quantitative classification of igneous rocks is proposed by E. T. Hodge, and published with a large chart in a University of Oregon Publication (Geology Series, vol. 1, No. 2, 1927). Four 'classes' based on the percentages of felspars plus felspathoids are plotted in four sectors of a circle. Each is divided radially into nineteen 'orders' based on the ratios of orthoclase to other felspars. Finally, the classes and orders are divided (by concentric belts) into seven 'ranges' based on the principle of silica saturation, beginning with quartz rocks on the outside and ending with 'metal' rocks on the inside. Any rock can therefore be placed somewhere in the resulting subdivisions, all of which can be represented on a single sheet. The arrangement is such that the quantitative mineral composition gives approximately the chemical composition. This is expressed on the chart by contour lines of percentages of the chief oxides, and it is claimed that within reasonable limits either chemical or mineral composition will place a given rock in the same pigeon-hole. There is nothing fundamentally new in the scheme proposed except the arrangement, which, however, is ingenious rather than illuminating.

BITUMINOUS SANDS OF ALBERTA.—Part 2 of the Report of the Scientific and Industrial Research Council of Alberta on the famous bituminous sands of that province, by Messrs. K. A. Clark and S. M. Blair, has now appeared, following their earlier publication on the occurrence of these resources. The problem of separation of the bitumen from the sand is not an easy one for large-scale practice, and it has been part of the policy of the Research Council to devote considerable time and money to its solution. This Report is to be read as a summary of progress and, in point of fact, is a valuable résumé of knowledge derived from comprehensive testing and experiment. Bituminous sands of the kind described are valuable both as raw materials and as sources of bitumen. In the latter connexion the chief advantages of separation are that the market available to bitumen is now more extensive than that available to the impregnated sand, and that since the freight charges on the sand are much greater than those on the bitumen alone, an artificial restriction to output is thus created. Furthermore, the manifold uses of free bitumen give to this commodity an advantage over its occurrence in the crude sand-state, in which form it is only suited to the construction of pavements and other wearing surfaces, and then only after special treatment. The authors describe the well-known hot water separation process, but dismiss it in favour of treatment of the sand with hot dilute sodium silicate solution agitated in excess of hot water, from which complete separation of the sand from the bitumen results. This procedure obviously has great practical possibilities, and though it is still in an experimental stage, it would seem as if the problem of asphaltic sands were well on the way to solution at last. The Report gives much detail of both the method and the plant employed in the work, and early industrial developments are foreshadowed.

THE BREADTH OF X-RAY SPECTRA.—There seems now to be little doubt that the great breadth observed in the lines of a number of X-ray spectra is real, in the sense of being atomic, and not instrumental in origin, but its large magnitude, of the order of ten times that to be expected from classical considerations of the damping of vibrations, is the more disconcerting from the fact that the decay of the light from hydrogen positive rays follows the classical laws fairly closely. The factors which might come into play with radiation of high frequency have been reviewed by D. Coster in the *Zeitschrift für Physik* of Nov. 18, where he has considered, amongst other effects, the possibility of an apparently simple line being actually an unresolved multiplet or a species of band, without, however, coming to any definite conclusion. He has been able to adduce some evidence that the natural breadth arises partly within the atom, and has pointed out a rule which holds for the relatively few lines that have been examined, to the effect that the more eccentric an electron orbit corresponding to a given energy level, the less well defined is a line arising from a transition involving that orbit.

RADIO OBSERVATIONS DURING TOTAL ECLIPSE.—An interesting account of observations made during the total eclipse of June 29 last is given in *L'Onde Électrique* for Sept. 6, by H. S. Jelstrup. A large 'tilting frame' was erected at Nordre Langen in Norway, longitude 11° 51′ east of Greenwich, which was approximately in the centre of the zone of totality. The observations were made on signals emitted from the relay station for Oslo at Hamar, which consequently had to travel an appreciable distance in the overhead 'conducting layer.' The first half of the eclipse was observed in favourable circumstances, but clouds interfered with the later observations. There was a large number of sunspots, and the instants at which these were eclipsed was accurately known. The intensity of the radio signals received from Hamar was read accurately by a micro-ammeter. There was a sudden increase in the ammeter reading at the moment before totality, and this was maintained, with the exception of a few rapid and sudden fluctuations, until after the period of totality. The ammeter gave its maximum reading at the moment after totality. The most obvious explanation is that the increase is merely a night effect produced by the lunar shadow on the conducting layer. The analogy with the effects produced by the setting sun on radio signals is perfect. The mean intensity of the ammeter readings on the day of the eclipse was much greater than on the following day. Whenever the lunar disc covered a sunspot a strong rhythmical disturbance was produced. This was very pronounced when the sunspot was near the centre of the sun's meridian facing the earth. The moon interrupted sharply the radiation proceeding from the sunspot and, after the time required for the radiation to travel from the moon to the earth, produced a disturbance in the waves radiated, and probably therefore in the conducting layer. There are indications that the moon produces a deviation effect on the rays coming from the sun as it approaches it. Hence at the time of the new moon, similar radiophonic effects are probably produced.

CONDUCTIVITY OF MOLTEN GLASS.—It has been known for many years that glass when heated to a temperature above 200° C. is sufficiently fluid to act as an electrolytic resistance. It is known that the passage of the current is due to the motion of the sodium in the glass. Experiments have proved that various metals when used as electrodes migrate into the glass, which thus becomes curiously marked. It is also known to electricians that an excellent arc can be maintained between glass electrodes when the alternating pressure has a sufficiently high frequency. Hitherto, however, very little information has been available with regard to the conductivity of glass when in the molten state. This property of glass is discussed in a paper by F. F. S. Bryson read to the Society of Glass Technology on June 2 last and recently published. He finds that when an electromotive force is applied to suitable electrodes immersed in molten glass, the current which passes through the glass between the electrodes rapidly diminishes for about a minute and then diminishes gradually until the steady state is reached: This is due to a number of bubbles forming in the molten glass next the positive electrode. These bubbles are the products of electrolysis, and as they gather round the electrode they partly insulate it, thus causing the current to fall. By breaking the battery circuit it is easy to measure the back electromotive force due to the polarisation. With alternating currents of ordinary frequencies the polarisation effects are much reduced, but gas bubbles are still formed. When platinum electrodes are used, the passage of the current is accompanied by a continuous succession of minute flashes. In order to diminish the polarisation effects and so enable approximate values of the conductivity at various temperatures to be measured, the author used high frequency currents. Interesting results with various kinds of glass are obtained, the conductivity increasing enormously with the temperature. The results are of importance in practical work as they show a connexion between viscosity and conductivity, and thus indicate the possibility of using recording electrical instruments to measure the viscosity of the molten glass as it flows from the tank.

THE ATOMIC WEIGHT OF ANTIMONY FROM DIFFERENT SOURCES.—The October issue of the *Journal of the Chemical Society* contains a paper by K. R. Krishnaswami, giving the results of a determination of the atomic weights of five samples of antimony. The metal was extracted from stibnite and cervantite from India and Burma and from Kahlbaum's antimony trioxide, as the trichloride, which was converted into the oxide and reduced. Antimony tribromide was then prepared in an atmosphere of nitrogen and the bromide estimated as silver bromide. The results ranged from 121·744 to 121·754 and are in good agreement with those of other workers in recent years. Muzaffar in 1923 obtained values varying from 121·444 to 122·374, using antimony from different sources, but his method appears, according to Krishnaswami, to be more difficult in practice than the one outlined above.

CONSTRUCTION OF DAMS.—In the usual types of dam—arched and otherwise—employed for power or irrigation purposes, provision has to be made for running away the surplus water retained during flood periods and periods of minimum demand, because if the water were simply allowed to run over the sill and fall hundreds of feet below, it would seriously impair the structure of the dam. Hence tunnels, derivation canals, etc., have to be arranged for, often at great expense. To overcome these difficulties, two French engineers, Messrs. Mesnager and Veyrier, have invented and patented a new type of arched dam which is being tried out in the barrage of the Upper Dordogne at Marège. In this type, instead of the direct fall from the sill to the lower level, the fall is split up into sections of 30-50 ft. in height by a number of partitions forming retaining basins which break the force of the water due to the eddying effect set up. These partitions are comparatively thin, and in order to ascertain whether they would stand up to the pressure of the water, experiments were carried out on small-scale models; and, by using mercury as the test liquid, the same effect was obtained as would be caused by the high pressure of water on the walls of the full-scale dam. According to *La Nature* of Dec. 1, in which the experiments are described, the tests have shown that the walls of the dam as actually designed will have a coefficient of safety of from 4 to 5. The experiments are judged of sufficient importance in France to be supported by generous grants from certain Government departments.

Prize Awards of the Paris Academy of Sciences.

AT the annual public meeting of the Paris Academy of Sciences the prizes and grants awarded in 1927 were announced as follows:

Mathematics.—The Francœur Prize to Georges Cerf, for his work on partial differential equations.

Mechanics.—The Montyon Prize to Dimitri Sensaud de Lavaud, for his work on the steering of motor-cars: the Poncelet Prize to Henri Villat, for his works on the mechanics of fluids.

Astronomy.—The Lalande Prize to Vincent Nechville, for his researches on star streams: the Valz Prize to Lucien d'Azambuja, for his work on sunspots, the solar prominences, and chromosphere: the De Pontécoulant Prize to Emile Paloque, for his work on the analytical theory of the movement of the Trojan planets.

Geography.—The Gay Prize to Henri Humbert, for his work in Madagascar: the Tchihatchef Prize to Jean Delacour and Pierre Jabouille, for their ornithological work in Indo-China.

Navigation.—The prize of six thousand francs between André Courtier (2500 fr.) for his work on hydrographical data and the prediction of tides: Pierre Changeux (2500 fr.) for his general study of the dynamics of ships or apparatus utilised in marine or air navigation: Edouard Davaux, for his "Cours d'electrotechnique": the Plumey Prize (in equal parts) between Etienne Hugé, for his memoir on the pulverisation and combustion of mazout in marine boilers, and Marcel Gautier, for his memoir on the utilisation of the Diesel motor.

Physics.—The Gaston Planté Prize to Gabriel Foëx, for his work on magnetism: the Hébert Prize to Pierre Sève, for his work on alternating currents: the Henri de Parville Prize to Paul Girault, for his work in electrotechnics: the Hughes Prize to Georges Reboul, for his researches on the radiation of badly conducting bodies through which an electric current is passing: the Pierson-Perrin Prize to Fernand Holweck, for his work on X-rays with wave-lengths between 14 A. and 500 A.: the Clément Félix Prize to Alexandre Dauvillier, to assist him in his researches on X-rays of great wave-length with special reference to their biological properties.

Chemistry.—The Montyon Prize (Unhealthy Trades) to Emile Kohn-Abrest (2500 fr.) for his work on poisonous gases, and an honourable mention (1500 fr.) to Edmond Rolants, for his book, "Les eaux usées": the Jecker Prize (in equal parts) between Georges Chavannes and André Kling, for the whole of their work: the Cahours Foundation to Clément Duval, for his work on nitrates: the Houzeau Prize to Augustin Damiens, for his work on the existence of bromine in animals and on the phenomena of allotropy.

Mineralogy and Geology.—The Cuvier Prize to Emile Argand, for his work on structural geology, and especially his researches on the Pennine Alps: the Delesse Prize to Charles Jacob, for the whole of his geological work: the Victor Raulin Prize to Fernand Daguin, to assist in the publication of his memoir on the geology of northern Morocco: the Joseph Labbé Prize to André Demay, for his geological work on Pechelbronn petroleum, Carthagena, and Huelva.

Botany.—The Desmazières Prize to V. Likhité, for his book on researches on the development and biology of some Ascomycetes: the Montagne Prize to Adrien Davy de Virville, for his work in experimental morphology relating to the mosses: the dé Coincy Prize to Pierre Bugnon, for his botanical work: the Rufz de Lavison Prize to Lucien Plantefol, for his biological study of the moss *Hypnum triquetrum*.

Anatomy and Zoology.—The Da Gama Machado Prize to Henri Neuville, for his work on the skin of the elephant and mammoth: the Savigny Prize to Maurice Langeron, for his pathological researches in Africa, Crete, and the Eastern Mediterranean.

Medicine and Surgery.—Montyon Prizes to Raoul Bensaude (2500 fr.), for his work entitled, "Traité d'endoscopie, rectoscopie, sigmoidoscopie": to Henri Carré (2500 fr.), for his "Recherches expérimentales sur une ectodermose neurotrope du chien: la maladie des chiens": to Constantin Levaditi (2500 fr.), for his work entitled "L'herpes et le zona, ectodermoses neurotropes." Honourable mentions (1500 fr.) to Jean Barotte and Achille Urbain, for their memoir "Étude des teignes du cheval et de l'immunité dans les teignes expérimentales": to Jean Verge, for his experimental researches on a dipthero-variolic affection of birds, and to Christian Zœller, for his researches on diphtheria. A citation to Émile Frache, for his work, "Les fouets et le mouvement des bactéries," and to Gustave Lesbouyries, for his work on the tuberculosis of the domestic carnivora.

The Barbier Prize to André Léri, for his work on affections of the bones and articulations: the Bréant Prize to Charles Dopter and Paulin Vezeaux de Lavergne, for their work on epidemiology: the Godard Prize to René Herpin, for his biological researches on the reproduction and development of some polychætal annelids: the Chaussier Prize to Edmond and Etienne Sergent, for their twenty-five years' work on the study and prophylaxy of paludism in Algiers: the Mège Prize to Félix Ramond, for his book on the diseases of the stomach and duodenum: the Bellion Prize to Jean Rieux, for his work on latent pulmonary tuberculosis; Grégoire Ichok receives an honourable mention: the Larrey Prize to Jean Jacquemart and Charles Clavelin, for their memoir, the military health service in times of peace and of war: the Argut Prize to André Charles Guillaume, for his work on light radiations in physiology and therapeutics.

Physiology.—The Montyon Prize to Louis Merklen, for his memoir on the rhythm of the heart during muscular activity, especially when due to games: the Pourat Prize to Antoine Magnan, for his work on the mode of flight of birds with application to the construction of aeroplanes: the Philipeaux Prize to Mlle. Eudoxie Bachrach, for the whole of her work in experimental physiology, with an honourable mention to Marc Jacot for his memoir on glycogen, adrenalin, and insulin.

Statistics.—The Montyon Prize to Jean Gérard, for his book on ten years of industrial effort.

History and Philosophy of Science.—The Binoux Prize to Henri Daudin.

Works on Science.—The Henri de Parville Prize to Fernand Monpillard (2000 fr.), for his book, "Macrophotographie et microphotographie," and Mme. Valentine Allorge-Gatin (1000 fr.) for the "Dictionnaire de botanique," by (the late) Ch. L. Gatin.

Medals.—The Berthelot medal to Emile Kohn-Abrest, Clément Duval, and Augustin Damiens.

General Prizes.—The Grand Prize for Physical Sciences to Georges Bohn, for his work in biology and comparative physiology: the Alhumbert Prize to Henri Longchambon, for his researches on triboluminescence: the Lallemand Prize to André Lwoff, for his work on the pigments in Copepods: the Maujean Prize to Raymond Sabouraud, for his work on the cure of ringworm: the Petit d'Ormoy Prize (Mathematical Sciences) to Ernest Vessiot, for the whole of his work: the Petit d'Ormoy Prize (Natural Sciences) to Lucien Cuénot, for his zoological work: the Le Conte Prize to Alexandre Yersin, for the whole of his work: the Parkin Prize to M. and Mme. Jacques Tréfouel, for their work on certain carbon compounds and their therapeutic action: the Saintour Prize to Stanislas Zaremba, for his work in mathematical analysis: the Lonchampt Prize (in equal parts) between André Liot, for his memoir on the culture of the pyocyanic bacillus in chemically defined media, and Michel Machebœuf, for his researches on the rôle of nickel and cobalt in animals and on the phosphorus compounds of the blood: the Wilde Prize to Jacques Duclaux, for the whole of his work: the Gustave Roux Prize to Jacques Fromaget, for his geological work in Annam: the Thorlet Prize to Adolphe Richard.

Special Foundations.—The Lannelongue Foundation between Mmes. Cusco and Rück: the Hélène Helbronner Prize to Mme. Schrader.

Prizes of the Grandes Écoles.—The Laplace Prize to Marcel Alliot: the L. E. Rivot Prize between Marcel Alliot, André Ligouzat, Raymond Cheradame, and Charles Feyrabend.

Funds for Scientific Research.—The Trémont Foundation to Marcel Jobelot, for his apparatus for the automatic inflation of captive balloons: the Gegner Prize to Francisque Dumont, for his work in geometry: the Hirn Foundation to René Fabre, for his work relating to fluorescence and its applications in analysis and in biology: the Henri Becquerel Foundation to Louis de Broglie, for his work in wave mechanics, atomic structure of matter and radiation: the Charles Bouchard Fund to Gustave Rappin, for his work on cancer and tuberculosis: the Pierre Lafitte Prize to Henri Abraham, for the whole of his work in radio telegraphy: the Roy-Vancouloux Foundation to A. Borrel, for his work on cancer.

Anti-Malarial Measures in Europe.

THE second general report of the Malaria Commission of the League of Nations, recently published, deals with "Principles and Methods of Anti-malarial measures in Europe." The report is divided into three sections. No. 1 gives a summary of the Commission's views on measures for dealing with malaria in Europe; No. 2 is entitled "Arrangements for studying Malaria"; and No. 3, "Prevention and Control of Malaria."

Section 1 is divided into sixteen parts, each followed by a short 'conclusion' of some half-dozen lines or usually less. These conclusions represent the 'average opinion' of the Commission based upon observation and consultation in many European countries. (A map of the study tours is provided.) They have an unexpectedness about them, very soothing to those who have been constantly told but have not entirely believed, that malaria could be, had been, or was being eradicated in all kinds of places and under all kinds of varying conditions from China to Peru, by this or that or the other panacea. Here is the first shock! "When the discovery of the mosquito cycle of the parasite was made, it was almost universally believed that a single simple method had been put within our grasp, capable of application in all malarious districts. Since then nearly three decades have passed, and such a method is still to seek." But the following is still more disturbing. "The history of special 'anti-malarial campaigns' is chiefly a record of exaggerated expectations followed sooner or later by disappointment and abandonment of the work."

Whether we agree completely with these estimates or not, there can scarcely be any doubt in the minds of those who have pondered over the matter, "that the only prospect of real progress lies in the renewed activity in the continuous study of the disease in all its aspects." We well remember the time when it was considered hyper-scientific to urge that anti-mosquito measures should be confined to killing those mosquitoes known to transmit malaria. It was considered to be more 'practical' to destroy all mosquitoes in one great holocaust.

How refreshing the idea that it is not always necessary to deal with malaria by a method arising directly out of the knowledge that the disease is transmitted by mosquitoes, and how sane the advise that "the treatment of malaria-infected persons is one of the most important measures even from the point of view of prevention."

The subject of 'Bonification' is discussed at length. The Italians do not regard large bonifications as an anti-mosquito measure, and they know that such a bonification may increase the abundance of Anopheles in the area reclaimed; but bonification means a better standard of life, and when that is attained, malaria tends, more or less quickly, to lose its importance as a cause of sickness or death. It would take too long to argue here that bonification has been the cause of the disappearance of malaria from England. Bonification, education, is perhaps the fundamental factor in anti-malarial measures. The anti-malarial factor in general schemes of bonification is the change in the conditions of life of the inhabitants. It has been said that "Le remède du paludisme est dans la marmite." It certainly lies in the schools. We welcome this report as a sane corrective to the exaggerated claims that are often made for this or that anti-malarial measure. The third portion of the report discusses various anti-malarial and anti-mosquito measures, such as the use of quinine and larvicides such as Paris green and liquid paraffin.

This second report is as stimulating as the first report issued in 1926. A summary of it by Lieut.-Col. S. P. James will be found in the *British Medical Journal* for Aug. 27, 1927.

Stereoscopic Photographs of Crystal-Structure Models.

A VERY handy little folding stereoscope has been placed on the market by Messrs. Adam Hilger, Ltd., under the name of a 'camerascope,' together with a series of double (stereoscopic) photographs of crystal-structure models, prepared under the direction of Sir William and Prof. W. L. Bragg, to illustrate the more striking and fundamental results of the X-ray analysis of crystals. Both the instrument, when its three hinged parts are folded together (the two outer ones upon the middle basal part), and the forty-one cards on each of which a complementary stereoscopic pair of photographs is printed, fit neatly into a cardboard box so small (5 in. × 4 in. × 1¼ in.) as to go conveniently into the coat pocket. As regards the instrument itself, the front plate of the three thin metallic (blackened) parts, which is arranged upright at right angles to the basal part when unfolded, carries the two stereoscopic lenses, and has a hole of suitable shape and size cut out of it to admit the nose; while the corresponding back-plate, also upright when opened out, is the stage and is fitted with suitable grooves and retaining guides for the reception of any one of the picture-cards, which are 4¼ in. × 3¼ in. in size.

On placing one of the cards in position, and bringing the instrument so close to the face that the lenses are close to the eyes, one sees the model of some crystal-structure or other, or an instrument (X-ray spectroscope, for example)—whatever it is that is photographed on the card—standing out in the three dimensions of space, as if one were looking at the actual object itself. Users of reading spectacles are recommended, and will find it necessary, to retain them, as no adjustment of the lenses is arranged for, the focus provided being that for normal vision.

Of the forty-one cards supplied, thirty-five are stereoscopic pairs of photographs of models, representing the crystal structure of the more important substances which have been satisfactorily analysed by means of the X-ray spectrometer or spectrograph. Among them are rocksalt, fluorspar, diamond, zinc blende, iron pyrites, spinel, calcite, aragonite, ruby or sapphire, graphite, ice, quartz, barytes, beryl, chrysoberyl, lithium potassium sulphate, cæsium chloride, naphthalene, tartaric acid, and racemic acid. Among the rest are stereoscopic photographs of the Bragg X-ray spectrometer, and of the X-ray spectrograph of Dr. Müller, the latter as arranged in three different ways, for the Debye powder method, the Bragg method, and the Laue and rotating crystal methods.

This use of stereoscopic pictures to represent objects, and in particular models of crystal structure, in relief in the three spatial directions, which is the next best thing to seeing the objects themselves, is not new. Prof. P. von Groth, the veteran crystallographer of Munich, in 1921 issued with his book on crystallography ("Elemente der physikalischen und chemischen Krystallographie") just such a series, twenty-five in number, of stereoscopic picture cards, a little larger than those issued by Messrs. Hilger, packed in convenient pockets on the inside of the front and back covers of the book. These Groth photographs can be used quite well with Messrs. Hilger's little stereoscope, provided the size of the cards be somewhat reduced to fit the stage, by cutting away superfluous margins, the photographs themselves being only very slightly larger than the Hilger ones, to fit a stereoscope of ordinary standard size.

The Hilger instrument is wonderfully effective, and should prove both useful and instructive to all who endeavour to follow the results of X-ray crystal analysis, but have not the immediate opportunity at hand of seeing the actual models or instruments themselves. A. E. H. TUTTON.

University and Educational Intelligence.

HULL.—Mr. T. R. Ferens has given a further sum, of £22,500, to the newly established University College. This brings Mr. Ferens' gifts to the College to about £300,000. He has asked that £20,000 of his latest benefaction should be set aside for endowing a chair. The foundation stone of the new buildings will be laid on April 28, when the Duke and Duchess of York will visit Hull.

Mr. A. C. Hardy, zoologist to the recent *Discovery* expedition to the Antarctic, will be the first professor of zoology at the University College.

THE first professorship of the geology of fuel (petroleum and coal) at a German technical school has been created at Freiberg in Saxony. The occupant is to be Dr. Otto Stutzer, who has also been elected director of the new fuel institute at the School of Mines.

THE annual report for 1926–27 of the Battersea Polytechnic, of which Mr. G. F. O'Riordan, formerly principal of the Leicester College of Technology, is now principal, shows that the total enrolment during the session was 3019, of whom 449 were full-time students, including 230 (the highest enrolment for many years) in the Training College of Domestic Science Teachers. The number of students preparing for university degrees was 219, and the number of degrees obtained was 37, including two Ph.D. and two M.Sc. degrees. A substantial amount of research work was done by the staff and students.

FROM the Hokkaido Imperial University of Japan we have received a volume published to commemorate the fiftieth anniversary of the founding of the Sapporo Agricultural College in which the University had its origin. The college was established under the guidance of Dr. W. S. Clark, of the Massachusetts State Agricultural College, who came over from America in 1876 for the purpose, and for eight months controlled its administration. For some years the college remained under American tutelage, but by 1893 all foreign guidance had been dispensed with and the professors were all Japanese. The University's indebtedness, however, to the Americans who shaped its beginnings is gratefully recognised, and the memory of Dr. Clark, in particular, is cherished with enthusiasm. It is noteworthy that his influence was strongly tinctured with religion. He introduced the Bible as a medium of literary and ethical instruction, and conducted daily religious exercises. The University comprises now schools of agriculture and forestry, medicine, technology, and fishery; its instructional staff numbers 240, its student enrolment exceeds 2000, its farms cover 15,000 acres, it has 245,000 acres of experimental forest lands, and its budget exceeds three million yen. With the exception of three instructors in English (all from the United States) and two in German, the staff is exclusively Japanese.

IN "Universities in the United States" (University of London Press, price 2*s*.), Dr. Edwin Deller, Academic Registrar of the University of London, describes impressions received in the course of a three-months' tour in the spring of 1926 undertaken by him at the request of the Laura Spelman Rockefeller Memorial trustees. His tour embraced institutions in the east and middle west and in California. His dominant impressions are concerned with the process of popularisation which has been such a marked feature of the recent history of university education in America. The difficulties involved in dealing with the vast multitude of students who come up imperfectly prepared and with no clear objective in mind are, he found, being faced with admirable courage, energy, and resource. He was much struck by the combination of stimulating faith in the universities, with frank recognition of their shortcomings and anxiety to trace these to their sources. He found a general desire to learn from and profit by the experience of other countries. The strongest feature of the American university is the provision for the graduate student. This has already helped to establish the prestige of America in universities in other countries, and promises even greater developments in the near future. In this connexion attention is directed to the tendency observable in some quarters to regard the education of the undergraduate as a task unworthy of the energies of a great university. English experience suggests, Dr. Deller points out, that to bear their best fruit undergraduate and graduate studies flourish best together, but conditions are more favourable in the United States for the experiment of limiting the activities of some universities to graduate work.

Calendar of Customs and Festivals.

January 18.

EPIPHANY AND OTHER OBSERVANCES OF THE GREEK CHURCH.—As the Greek Church retains the Old Style Calendar, Epiphany falls twelve days later than in western Europe. It is a festival held in great regard throughout the Greek Church; but in Rumania the baptism of Jesus Christ is celebrated with special solemnity as one of the most important feasts of the year. It is to be noted that in both ecclesiastical ritual and in popular custom, the observances of this day involve a ceremonial connected with water. In Bukarest, after the Church service a solemn progress, in which the royal family takes part, is made to the River Dambovitza, where, after a service, a gold and enamelled cross is thrown into the river. Men standing by, stripped to the elaborately embroidered shirts which form a characteristic part of the gala national costume, jump into the river, and the one who retrieves the cross receives a present from the king.

In Constantinople a similar procession of dignitaries of the Greek Church goes to "bless the waters of the Bosporus," and a similar religious or semi-religious ceremonial is observed in southern Greece, where it is known as "diving for the cross." Some light is thrown upon the custom when the immersion is involuntary, as in Macedonia, where it is the custom to thrust someone into the water—a river, the sea, or even a pond or well, the victim receiving a reward for his immersion. On emerging from the water he should sprinkle as many of the bystanders as possible with drops of water. The reward is spent on a banquet.

This popular custom suggests a remote origin in a propitiatory offering to the spirit of the waters, while sprinkling the bystanders with the drops of water is in keeping with the belief in the special 'healing efficacy' of the water at this time of the year. Hence also the general desire for baptism at this season. In the Ethiopian Church, all baptisms of the year were reserved for this day. In Rumania, where it is also a specially favoured day for baptism, children baptised at the same time are known as 'brethren of the cross,' and throughout their lives stand in a specially intimate relation one to another. Should one be dying, unless his 'brother' is chained to him and solemnly released by a third person, the 'brother' will also suffer an early death.

EPIPHANY IN MACEDONIA.—Here the twelve days leading up to Epiphany are a period when magical influences are peculiarly potent. On the eve of Epiphany a general cleaning up of the house takes place, and the ashes which have been allowed to accumulate on the hearth are cleared away. With these go the evil influences lurking in the house, and especially the Karkantzari, malicious fiends at night, of human form by day. These beings would appear to be related to the werewolf. No marriages are celebrated while they are about. They may perhaps be credited, therefore, with similar powers to those of the witch who, by 'tying knots,' may cause impotence and render marriage unfavourable at critical seasons.

January 19. (O S. January 7.)

FEAST OF ST. JOHN THE PRECURSOR AND BAPTIST.—This festival is observed in the Balkans (Macedonia) by a custom analogous to the carnival customs celebrated later in the Ægean. Parties of old men dressed in goat's skin or old clothes, and girt with chains of bells, parade the streets collecting money by terrorising rather than by amusing. Both their attire and the feeling they aim at inspiring would relate them to the awestriking powers of Nature, later symbolised by Pan and his attendants. Milder in form and character are the 'precursors,' each heading a band of eight or ten men, who go from house to house, and are regaled at loaded tables. They then take away everything they have not already consumed in skins and bottles carried for them by boys. In return for their entertainment, the leader improvises highly eulogistic songs on each member of the family.

In Rumania, on the night of Jan. 6 (O.S.), boys obtain from the priest the aspergil, partly composed of basil (a peculiarly 'holy' plant in Balkan belief), used that morning in the Epiphany ceremonial of scattering holy water after the service on bystanders outside the church. They then proceed to visit the houses of the village, and each member of the household is whirled round and round. On the next morning, Jan. 7, they stand at the door of the church and do the same to each one of the congregation, as well as the priest, as they enter. Beyond attributing it to a pagan origin, no explanation has been offered for this custom, but as the solemn canticle of the Epiphany ceremony is sung on entering each house, it is clearly an attempt to extend the sanctifying influence to each member of the community, while the whirling round has all the appearance of a fertility custom.

January 21.

ST. AGNES, ROMAN VIRGIN AND MARTYR, whose chastity was miraculously preserved against all assault, when consigned to the stews of Rome on her refusal to marry the son of the prefect. He, being struck dead for his attempt on her, was restored to life by her prayers. By popular clamour she was condemned to the flames as a witch, but when they refused to consume her she was beheaded on the pyre. Eight days after her martyrdom she appeared to her parents in a company of virgins with a lamb by her side. Hence the lamb is her symbol, and each year in the Basilica to her memory at Rome twin lambs are blessed, and from their wool the pallium of the archbishops is woven.

In view of the history of the saint, it is not surprising that in popular belief her festival, or rather the eve of her festival, should be associated with divination in relation to marriage. Burton, in his "Anatomy of Melancholy," speaks of maids fasting on St. Agnes Eve, and Aubrey gives directions how by sticking pins in a sleeve to the accompaniment of paternosters, a dream of the future partner in marriage may be obtained. The belief was generally prevalent throughout England. A ritual was observed and an invocation addressed to St. Agnes before retiring. Certain precautions had to be observed, such as that no man should kiss the inquirer on that day, and she should wear a clean white shift. In Scotland the custom was that a number of those seeking to know their future husband or wife met at midnight. Each proceeded alone to a certain cornfield, and threw in some grain, repeating a verse invoking the saint. That night the saint granted him or her a vision of the future partner in a mirror.

January 22.

ST. VINCENT'S DAY.—One of the numerous days at about this time of the year associated with weather lore. The return of spring was a matter of special moment to an agricultural or pastoral community. Hence the exhortation to "remember if the sun shine on this day."

Societies and Academies.

CAMBRIDGE.

Philosophical Society, Dec. 5.—**W. H. Mills** and **K. A. C. Elliott**: Molecular dissymmetry dependent on restricted rotation about a single linking. The optically active forms of benzenesulphonyl-8-nitro-1-naphthylglycine. The ordinary criteria which enable the existence of molecular dissymmetry in a compound to be predicted from its structural formula do not indicate that perididerivatives of naphthalene of the type  $C_{10}H_6(NR_1R_2)(NO_2)$ should be obtainable in enantiomorphous modifications. It has proved possible to demonstrate experimentally that this type of dissymmetry actually exists in the benzenesulphonyl derivative of 8-nitro-1-naphthylglycine.—**F. G. Mann**: Note on the configuration of the tetrammino-platinous complex. The uniplanar configuration was first allotted to the tetrammino-platinous complex by Werner in order to explain the existence of two forms of dichloro-diammino-platinum $[Cl_2Pt(NH_3)_2]$. Reihlen and Nestle, however, consider these two forms to be not isomeric but polymeric, and assign the tetrahedral configuration to the platinous complex. It seems highly probable that certain complex platinous salts have the tetrahedral configuration, and that the configuration of any particular complex salt is determined mainly by the nature of the co-ordinating groups.

COPENHAGEN.

Royal Danish Academy of Science and Letters, Nov. 4.—**P. O. Pedersen**: Composition, pressure, temperature, and electrical conductivity of the air at high altitudes in the light of radio-wave propagation.

Nov. 18.—**Niels Bohr**: The quantum postulate and the recent development of atomic theory. The dualism which characterises the formulation of the quantum theory has received much illumination through the recent great progress of atomic theory. In the present state of science, this dualism would seem unavoidable and may be regarded as a direct expression of the fundamental limitation of the ordinary principles of classical physics postulated by the quantum theory.

Dec. 2.—**Johs. Lindhard**: The elasticity of skeletal muscles. Experiments show that the coefficient of elasticity decreases when the muscle is stimulated.

GENEVA.

Society of Physics and Natural History, Nov. 3.—**R. Wavre**: The heterogeneous fluid mass in rotation and geodesy. The author demonstrates that Stokes's theorem relating to the Newtonian potential of a heterogeneous fluid mass in relative equilibrium $U_{ext} = F(S, \omega = c, M)$ can be extended to all cases where the angular velocity is a function of the distance from the axis, that is to say, to any planet of which the layers of equal density are horizontal at each point.—**W. H. Schopfer**: Physico-chemical researches on some parasites of fresh- and salt-water fishes. The experiments show that the parasites studied have a Δ very near that of the intestinal liquid of their host and also of that of the internal medium of the latter.—**L. Duparc, E. Molly**, and **A. Borloz**: Birbirite, a new rock. The authors have found in Abyssinia and in Serbia a quartz rock containing on the average 90 per cent. of silica, composed of grains of quartz, sometimes spherolitic, covered with a mass formed of quartz grains and isotropic material.—**M. Gysin** and **L. Duparc**: The phenomena of magmatic and secondary Uralitisation. The gabbro diorites of the northern Ural show a magmatic transformation of pyroxene into brown hornblende and a secondary transformation of the latter into a blue amphibole.—**A. Schidlof**: The geometrical representation of the mass of a material point in a universe of five dimensions. The author indicates a geometrical interpretation of the great difference which exists between the mass of the proton and that of the electron.—**Raoul Pictet**: Experimental demonstration of the potential of the ether. Its consequences in the physical theory of the properties of vapours and gases. The author completes the account of the subject given in the meeting of Oct. 20.

Nov. 17.—**G. Tiercy**: A new method for determining the form of the light curve of a variable star. The author measures on a photographic plate the lengths of the spectra and the widths of the lines. These two magnitudes are connected by a simple relation which allows of the construction of the light curve of a variable star.—**A. Brun**: The augite and chrysolite of Stromboli. The augites of Stromboli lend themselves to crystallographic measurements if the surface is cleaned by immersing for some seconds in hydrofluoric acid. They contain as inclusions chrysolites of small dimensions not permitting of exact measurement.—**A. Brun**: Change of the parameters of magmatic augite. If the edge (011) $(0\bar{1}1)$ is taken for the axis of x, y and z remaining the same, the law of Bravais is completely verified (the law connecting the frequency of the faces and their reticular density).—**Gr. Gutzeit**: A colour reaction of the vitasterins. A suitable solution of antimony trichloride and hydroxylamine hydrochloride allows a colorimetric estimation of the vitasterins and appears to permit of a separate estimation of the A and D factors.—**L. Duparc** and **E. Molly**: An Abyssinian augitite. This rock contains augite and magnetite as phenocrystals in a vitreous mass with grains of magnetite and microlites of augite. It contains 42 per cent. of silica.—**E. Briner** and **A. Van der Wijk**: The effect of moisture on the peroxidation of oxide of nitrogen. Experiments made with the reactions ammonia and hydrochloric acid, hydrogen and chlorine, oxide of nitrogen and chlorine, propylene and bromine, appear to show that the action of moisture is especially exerted in the formation of heteropolar compounds.—**R. Wavre**: A useful formula for geodesy. Supposing, in a fluid star in permanent movement of rotation, layers of equal density normal at each point to the field of gravity, the mean curvature of the surface at a point can be determined by means of the formula

$$\frac{dg}{dn} = Cg + \Delta Q - 4\pi f\rho.$$

—**R. Pictet**: A gas cycle transforming into energy the whole of the heat furnished to the cycle. According to the author, it should be possible to realise with the aid of a gas a cycle furnishing the total transformation of the heat utilised into mechanical work.

ROME.

Royal National Academy of the Lincei. Communications received during the vacation.—**A. L. Herrera**: Thermotropism and constants of the colpoids. Like mobile cells and microscopic organisms, colpoids exhibit positive thermotropism, this effect being due to increase in the osmosis, and to increased intensity of the currents on the membrane and of the chemical reactions on the heated side. Moreover, as regards their movements, colpoids are subject to minimum, maximum, and optimum temperatures.

The presence of lactose increases the osmotic pressure and determines the formation of enormous colpoids, which have the shape of horse-shoes and imbibe at their extremities.—L. Petri: Further investigations on the application of fluoroscopic analysis to normal and pathogenic vegetable tissues. Contrary to the indications of earlier experiments, the alcoholic extract of chlorophyll, carotin, and xanthophyll obtained from leaves killed by boiling water, always contains part of the photo-luminescent ingredient. The properties of this substance show that it must be placed among the glucosides.—R. Caccioppoli: Quadrature of plane and curved surfaces.—G. Supino: Influence of perforations on the elasticity of a plate. —V. Ronchi: Distortion: a new interpretation of an old experiment.—F. Ruda: Explanation of the 'green ray.' Julius has explained the observed long duration of the so-called green ray, in comparison with the theoretical duration, by assuming that, in the neighbourhood of the horizon, the atmosphere exhibits anomalous dispersion of the sun's light for the waves comprised between Fraunhofer's lines *E* (526·97 μμ) and *F* (486·06 μμ). A consequence of this assumption would be a sensible difference between the index of refraction of air devoid of, or poor in, ions and that of air rich in ions. The author's experiments fail to reveal any such difference. —M. L. Pagliarulo: Further researches on natural rotatory and refractive dispersion. The rotatory dispersion of monoisoamyl aspartate is distinctly anomalous and of the same type as that of monoethyl aspartate. Between the rotatory and refractive dispersions there exists a close relationship, which is not evident from the dispersion curves themselves, but is made manifest by calculating the finite differences of the indices for successive wave-length intervals and representing these graphically.—G. Mezzadroli and G Gardano: The formation of formaldehyde and sugars by the action of ultra-violet rays on alkali and alkaline-earth bicarbonates. These bicarbonates are decomposed by ultra-violet rays with velocities which are greatest for the calcium, and least for the sodium salt. The amount of aldehyde obtained is greater from ammonium bicarbonate than from the alkali bicarbonates, but the greatest yield of formaldehyde is furnished by calcium bicarbonate. —L. Fernandes: Investigations on sulpho-salts. (4) Certain derivatives of a hypothetical thioacquic acid. Various methods of preparation are available for obtaining parasulphomolybdates of the form $[\mathrm{H}_2(\mathrm{MoS}_4)_4]^{\mathrm{R}'}_{\mathrm{H}_4}$ which are the sulphur analogues of the paramolybdates. The ammonium compound decomposes readily, but is stable in the presence of ammonia.—B. Monterosso: Preliminary observations on the biology of the genus Scytodes (Walck) (Araneæ veræ, Sicariidæ).—A. Busacca: Histological changes encountered in the naphthalene cataract when the crystalline fibres are examined in a surviving condition. The first alterations in the crystalline fibres with animals to which naphthalene has been administered orally are intra-cytoplasmic and consist in the disappearance of the more refractive droplets in the cytoplasm of the more peripheral fibres. These droplets increase in number until they occupy the whole fibre, the chondroma at the same time breaking up and disappearing. The changes afterwards extend to the inner fibres.—G. Testi Dragone: Contribution to the study of the fluorescence of chlorochrome in ultra-violet rays. When exposed to the influence of ultra-violet rays, chlorochrome exhibits a red fluorescence of various gradations. This fluorescence is obtained *in vitro* only when the chlorochrome is in solution, but it is visible in the living chloroplasts.

Diary of Societies.

SATURDAY, January 14.

British Psychological Society (at Royal Anthropological Institute), at 3.—Dr. C. S. Myers: The Influence of the Menstrual Cycle on Muscular and Mental Efficiency. (An investigation carried out on behalf of the Industrial Fatigue Research Board by S. C. M. Sowton and Dr C. S. Myers.)—J. W. Cox: Mechanical Aptitude: Its Existence and Measurement.

Institution of Mechanical Engineers (Bristol Branch) (at Bristol).—Prof. C. J. Hawkes: The Marine Oil-Engine (Thomas Lowe Gray Lecture).

MONDAY, January 16.

Victoria Institute (at Central Hall, Westminster), at 4.30.—Dr. W. Bell Dawson. The New Testament Era in the Sequence of Prophecy.

Royal Geographical Society (at Lowther Lodge), at 5.—G. M. Lees: The Physical Geography of South-East Arabia.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith. A Review of Hunter's Experiments of Growth and Grafting, and the Interpretation of his Results in the Light of Modern Discoveries.

Railway Club (at 25 Tothill Street, S.W.), at 7.30.—Lieut.-Col. W. R. Mansfield: Timetables, Old and New.

Royal Society of Arts, at 8.—Dr. A. E. Dunstan: The Scientific Foundation of the Refining of Petroleum (Cantor Lecture) (I.).

Chemical Industry Club, at 8.—J. Hill: The City Churches.

Hunterian Society, at 9.—Dr. H. Kelly: Emergent Gynæcology (Hunterian Lecture).

Royal Society of Medicine (Social Evening), at 9.15.—Dr. Jane Walker: Saints, Medicine, and Surgery.

Institution of the Rubber Industry (Sales Section) (at Engineers' Club, Coventry Street).—C. Tullberg: Art of Window Dressing.

Institute of Brewing (London Section) (at Charing Cross Hotel).—J. Stewart: Malting Barleys of 1927.

University of Birmingham Chemical Society (at Birmingham University).—Prof. W. N. Haworth: Presidential Address.

TUESDAY, January 17.

Royal Institution of Great Britain, at 5.15.—P. R. Coursey: The Development of Dielectrics for Electrical Condensers (I.).

Royal Statistical Society (at Royal Society of Arts), at 5.15.

Royal Society of Medicine, at 5.30.—General Meeting.

Institution of Electrical Engineers (East Midland Sub-Centre) (at City Hall, Leicester), at 6.45.—A. H. Law and J. P. Chittenden: Higher Steam Pressures and their Application to the Steam Turbine.

Society of Chemical Industry (Glasgow Section) (at 39 Elmbank Crescent, Glasgow), at 7.—Dr. C. H. Lander: The Fuel Problem.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—Dr. T. Slater Price: A Résumé of Recent Work on the Effect of Adsorbed Ions on the Photo-sensitivity of the Silver Halides.

Institution of Automobile Engineers (Wolverhampton Centre) (at Engineering Club, Wolverhampton), at 7.30.—H. A. Watson: The Electrical Characteristics of Spark Gap and Sparking Plugs.

Society of Chemical Industry (South Wales Section) (at Technical College, Cardiff), at 7.30.—J. Pryde: Vitamins and Diet.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch), at 7.30.—J. Calderwood: Diesel Engine Drive for Generators and other Auxiliary Machinery on Board Ship.

Hull Chemical and Engineering Society (at Photographic Society's Rooms, Grey Street, Hull), at 7.45.—F. H. Peck: Hydro-electric Development in Brazil.

British Institute of Philosophical Studies (at Royal Society of Arts), at 8.15.—Dr. C. D. Broad: Main Problems of Ethics.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.30.—Prof. R. R. Gates: Amerindian Crosses in Canada.

INSTITUTE OF BREWING (Scottish Section) (at Caledonian Station Hotel, Edinburgh).—C. Ranken and J. R. Bell: Surface of Yeast as a Factor in Fermentation.

MINERALOGICAL SOCIETY.—Dr. L. J. Spencer: Potarite, a New Mineral discovered by the late Sir John Harrison in British Guiana.—Dr. H. V. Ellsworth: A Simple and Accurate Constant-Volume Pyknometer for Specific Gravity Determination.—W. Campbell Smith: The Optical Orientation of Labradorite from County Down (Ireland) determined by the Federov Method.

WEDNESDAY, JANUARY 18.

SOCIETY OF GLASS TECHNOLOGY (at College of Technology, Manchester), at 2.30.—W. W. Warren: The Design and Operation of Glass Furnaces.—P. Marson (based on a Paper by Prof. W. E. S. Turner): The Manufacture and Use of Glasshouse Pots.—Prof. W. E. S. Turner: The Refining of Glass.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Growth of Living Tissues under Experimental Conditions and the Bearing of the Knowledge thus obtained on Abnormal Growth of the Human Body.

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at 17 Fleet Street), at 5.30.—Eng.-Capt. E. C. Smith: Some Episodes in Early Ocean Steam Navigation.

INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.30.—H. A. Reed: Appliances for Handling Goods in Ports and Docks (Vernon-Harcourt Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.—W. Ellerd-Styles: Large Electric Baking Ovens.

INSTITUTE OF METALS (Swansea Local Section) (at Thomas' Cafe, Swansea), at 7.—W. T. Griffiths: Some Interesting Properties of Alloys of Nickel.

INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—G. E. Taylor: Electric Furnaces in Metallurgy.

MANCHESTER GEOGRAPHICAL SOCIETY (at 16 St. Mary's Parsonage, Manchester), at 7.30.—L. M. Butterworth: The Lancashire Glass Industry (Lecture).

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Annual General Meeting, at 7.40.—Presentation of Symons Medal to Prof. H. Hergesell.—Prof. H. Hergesell: The Observation of Clouds with Special Reference to The Safety of Aviation.—Sir Gilbert T. Walker: World Weather.

MERSEYSIDE AQUARIUM SOCIETY (at 1 Falkland Road, Egremont), at 7.30.—Rev. C. E. Y. Kendall: The Paper Aquatic Molluscs.

ROYAL MICROSCOPICAL SOCIETY (Annual Meeting), at 8.—Dr. J. A. Murray: Staining and Structure (Presidential Address).

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—H. M. Fletcher: Architecture of Provincial France (Lecture).

ROYAL SOCIETY OF ARTS, at 8.—A. H. Barker: Methods of Radiant Heating.

ENTOMOLOGICAL SOCIETY (Annual Meeting), at 8.

FOLK-LORE SOCIETY (at University College), at 8.—Mrs. F. Ayscough: A Calendar of Chinese Household Customs.

ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY (at Northampton Polytechnic Institute), at 8.15.—W. James: Polishing and Plating.

THURSDAY, JANUARY 19.

ROYAL SOCIETY, at 4.30.—R. S. Horning and A. H. K. Petrie: Enzymatic Function of Mitochondria in the Germination of Cereals.—S. Dickinson: Experiments on the Physiology and Genetics of the Smut Fungi.—P. H. H. Gray: Formation of Indigotin from Indol by Soil Bacteria.—Dr. R. A. Fisher: Triplet Children in Great Britain and Ireland.—Prof. J. W. H. Harrison: (a) A Further Induction of Melanism in the Lepidopterous Insect, *Selenia bilunaria* Esp. and its Inheritance; (b) Induced Changes in the Pigmentation of the Pupae of the Butterfly, *Pieris napi* L. and their Inheritance.—*To be read in title only*.—J. Piper: On the Evolution of the Vertebral Column in Birds illustrated by its Development in Struthio and Larus.—F. G. Gregory and A. S. Horne: A Quantitative Study of the Course of Fungal Invasion of the Apple Fruit and its Bearing on the Nature of Disease Resistance. Parts I. and II.—F. G. Gregory: The Differential Effect of the Ions of Three Salt Solutions on the Growth of Potato Plants in Sand Culture.—Sir Kenneth Goadby: Bacterial Proteins.—L. Rapkine and R. Wurmser: On Intracellular Oxidation-Reduction Potential.—Dr. F. W. R. Brambell: Development and Morphology of the Gonads of the Mouse. Part II.—Prof. R. C. Punnett: Linkage Groups and Chromosome Number in Lathyrus.

LINNEAN SOCIETY OF LONDON, at 5.—C. V. B. Marquand: On Capt. Kingdon Ward's Botanical Collections from the Eastern Himalaya and Tibet, 1924–25.—F. W. Edwards: Insect Collecting in the Southern Andes.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. J. F. Thorpe: The Significance of Unsaturation in Carbon Compounds (L.).

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—W. Ellerd-Styles: Large Electric Baking Ovens.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—Major W. S. Tucker: The Problem of Noise in Civil Aircraft and Possibilities of its Elimination.

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—T. Smith: On Toric Lenses and Canonical Forms in the Theory of Asymmetrical Optical Systems.—Dr. M. Herzberger: Some Remarks on an Extension of the Optical Cosine Law.—Tintometer, Ltd.: Demonstration of the Rosenheim-Schuster Colorimeter.

INSTITUTE OF METALS (Birmingham Local Section) (jointly with Birmingham Metallurgical Society and Staffordshire Iron and Steel Institute) (at Engineers' Club, Birmingham), at 7.—T. H. Turner: Heat Resisting Alloys.

INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry, East of Scotland Section) (at North British Station Hotel, Edinburgh), at 7.30.—Discussion on The Separation of Solids and Fluids.

CHEMICAL SOCIETY, at 8.—Prof. G. T. Morgan and H. Burgess: *cyclo*Telluropentane.—I. Vogel: Syntheses of Cyclic Compounds. Part II. Racemic and Meso Ethyl βγ-diphenylbutane-ααδδ-tetracarboxylate. Synthesis of a Truxinic Acid.—E. H. Farmer, C. D. Lawrence, and Prof. J. F. Thorpe: Properties of Conjugated Compounds. Part IV. The Formation of Isomeric Additive Dibromides from Butadiene.

LANCASTER ASTRONOMICAL AND SCIENTIFIC ASSOCIATION (at Storey Institute, Lancaster), at 8.—G. Dixon: Coal Gas Manufacture.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Chandos Street, W.), at 8.15.—Surg.-Commdr. D. H. C. Given: Some Health Problems of the Singapore Naval Base.

EUGENICS SOCIETY (at Royal Society), at 8.30.—F. C. Bartlett and others: Discussion on Innate Qualities in Social Classes.

INSTITUTION OF MECHANICAL ENGINEERS (Birmingham Branch).—Informal Discussion.

INSTITUTION OF MECHANICAL ENGINEERS (Manchester Branch).—L. H. Fry: Some Experimental Results from a Three-Cylinder Compound Locomotive.

FRIDAY, JANUARY 20.

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30.—M. G. Simpson: The Indo-European Telegraph Department.

ASSOCIATION OF ECONOMIC BIOLOGISTS (Annual Meeting) (in Botany Department, Imperial College of Science), at 5.—Presidential Address.

SOCIETY OF MEDICAL OFFICERS OF HEALTH (at 1 Upper Montague Street, W.C.), at 5.—Dr. W. Elliot and Prof. R. H. A. Plimmer: Recent Advances in the Knowledge of Food.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: A Summary of the Evidence, both Experimental and Clinical, of the Growth-controlling Functions of the Pituitary Gland.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at Liverpool University), at 6.—G. Fairrie: The Production and Refining of Cane Sugar.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Fifth Report of the Steam-Nozzles Research Committee.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—Dr. R. C. Fox: The Three Cathode Carbon Arc.

WEST CUMBERLAND SOCIETY OF CHEMISTS AND ENGINEERS (at Workington), at 7.—O. T. Jones: The Lubrication of the Automobile.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group Informal Meeting), at 7.—T. H. B. Scott: The Pictorial Aspect of Modern Buildings.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—S. Hopkins: Steam Accumulators.

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (jointly with Society of Dyers and Colourists (Manchester Section)) (at Milton Hall, Manchester), at 7.30.—Dr. A. E. Everest and J. A. Wallbrook: Azoic and other Insoluble Colours.

TUBERCULOSIS SOCIETY (at Royal Society of Medicine), at 8.—Dr. G. Jessel, Dr. A. P. Ford, Miss Lewis, and others: Discussion on the Work and Aims of Tuberculosis Care Committee and Kindred Agencies.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Prof. S. Russ, Dr. T. F. Cotton, Dr. Justina Wilson, and others: Discussion on Diathermy in Relation to Circulatory Disturbances, particularly in High Blood Pressure, etc.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir William Bragg: Photo-electricity.

SOCIETY OF DYERS AND COLOURISTS (Scottish Section) (at Glasgow).

SATURDAY, JANUARY 21.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. R. W. Chambers: Some Tudor Biographers (I.).

PHYSIOLOGICAL SOCIETY (in Department of Physiology, King's College).

PUBLIC LECTURES.

FRIDAY, JANUARY 13.

UNIVERSITY COLLEGE, at 5.—C. F. A. Pantin: Comparative Physiology. (Succeeding Lectures on Jan. 20 and 27, Feb. 3, 10, 17, and 24, Mar. 2, 9, and 16.)

MONDAY, JANUARY 16.

EAST ANGLIAN INSTITUTE OF AGRICULTURE (Chelmsford), at 7.—R. L. Cornell: Poultry Diseases.

TUESDAY, JANUARY 17.

KING'S COLLEGE, at 5.—Dr. J. A. Hewitt: Integration in the Nervous System. (Succeeding Lectures on Jan. 24 and 31, Feb. 7, 14, 21, and 28, Mar. 6.)

WEDNESDAY, JANUARY 18.

UNIVERSITY COLLEGE, at 4.—Prof. A. V. Hill: Muscle. (Succeeding Lectures on Jan. 25, Feb. 1, 8, 15, and 22.)

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.30.—Dr. R. Burrows: The Medical Practitioner in relation to the Administration of Justice.

THURSDAY, JANUARY 19.

UNIVERSITY COLLEGE, at 5.—Dr. R. J. Ludford: Cytology in Relation to Physiological Processes. (Succeeding Lectures on Jan. 26, Feb. 2, 9, 16, and 23.)

KING'S COLLEGE, at 5.30.—Dr. F. W. R. Brambell: The Development of Sex, with special reference to Recent Work on Birds and Amphibians. (Succeeding Lectures on Jan. 26, Feb. 2, 9, 16, and Mar. 1.)

SATURDAY, JANUARY 21.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Stone working in Ancient Egypt.

SATURDAY, JANUARY 21, 1928.

Land Drainage.

THE heavy rainfall and snowstorms of last month, culminating in the overflow of the Thames in London on Jan. 7, with grievous loss of life, has brought vividly before the nation the subject of the control and disposal of surplus water. In Great Britain, the problems, although serious, are not of the same magnitude as elsewhere. The disastrous Mississippi floods of last summer, and the extensive damage done around Bagdad when the Tigris broke its banks about two years ago, are illustrations of a menace the full force of which is happily spared us. In these cases the fundamental cause is the gradual raising of the river bed in its lower reaches by the suspended material brought down from the uplands and deposited when the speed of the current is reduced.

In the absence of measures of control, the river will frequently change its course, and may build up an extensive delta in the estuary. The difficulty is met by dredging, which is rarely able to meet the case completely, especially in extensive river systems, and reliance is placed mainly on embankments or levees for confining the river to its course. The embankments must be raised from time to time to keep pace with the silting up of the river bed, and eventually the normal water level may be several feet above the level of the surrounding land. In such conditions a break in the defences is disastrous, and the longer the catastrophe is in coming, the greater it is. The effect is felt most in the lower reaches of the river; but the causes extend over the full region of the catchment area. Every little stream, every small trickle of surface water, is contributing its small quota of suspended material to the main stream, and the engineer is in reality struggling against Nature's ceaseless modification of the topography of the land over the whole of the drainage area discharging into the river. The battle can never be won; an armed truce is all that can be hoped for, and man's energies are or should be directed towards postponing the evil day.

The necessity for co-ordination in such efforts is self-evident: it is worse than useless for the protection of one part of the area to be carried on as an isolated problem, independent of the conditions in adjacent areas; and yet in Great Britain this piecemeal method is still the rule rather than the exception. For a long time past, the problem of land drainage has been growing steadily more acute, and the enforced neglect during the years of the War brought matters to a head. Attempts were made in the Land Drainage Acts of 1918 and 1926 to secure improvements in co-ordination and grouping of the multitudinous drainage authorities, each of which is more or less a law unto itself. These acts were not satisfactory, quite apart from the question of lack of funds, and a Royal Commission was appointed in March 1927, with the Right Hon. Lord Bledisloe as chairman, to inquire into the present law and its administration, and to suggest any improvements that would lead to an efficient arterial drainage system without placing undue burdens on any particular section of the community. The Commission was ordered to report as soon as possible, and it has obeyed this instruction with commendable zeal: the Report [1] was issued last month.

The main recommendation is that a catchment area shall be regarded as one unit, and be under the control of its own elected central authority, that shall be responsible for the main channel of the river, the upkeep of which shall be a rating charge on the whole catchment area. The numerous drainage boards existing within any catchment area are to be reorganised and grouped as internal drainage authorities, which will levy their local rates for internal drainage, and be supervised by the catchment authority in order to secure co-ordination of effort. The Thames is regarded as a special case, and it is recommended that beyond constituting the Conservancy a drainage authority for the whole of the catchment draining into its present area of jurisdiction, no change should be made; the Port of London Authority would therefore continue to exercise control from below Teddington weir to the Crowstone. This suggestion may need modification in view of the recent floods in London.

The recommendations of the Commission are simple, and indeed obvious, but they are none the less sweeping in their effect. They reduce to a logical scheme the confusion that now exists. There are more than 360 drainage authorities of various types in England and Wales, many of them of great age. The earliest appears to be the Commission of Sewers for Romney Marsh, appointed in the reign of Henry III., and it covers the period when the land was settled in more or less isolated and self-supporting communities. Much of the low-lying part of the country, now occupied, was then wastes of marsh or fens that provided, until reclaimed in their turn, a ready and convenient accommodation for the drainage water from the settled areas. The fens of East Anglia provide the best example of this process. Reclamation on an extensive scale was begun in the seventeenth century in spite of the determined opposition of the fenmen, whose attitude can be judged from the following verse of a doggerel poem of the period:

> "The feather'd fools have wings to fly to other nations,
> But we have no such things to help our transportations;
> We must give place (oh, grievous case!) to hornéd beasts and cattle,
> Except that we can all agree to drive them out by battle."

It is not surprising that these difficulties, together with the lack of engineering resources, and the absence of much of the interdependence that now marks British agricultural life, should have resulted in the construction of many independent reclaimed areas, the drainage authorities of which would say, with Chesterton, "I don't care where the water goes, if it doesn't get into"—my land. This very natural attitude was reinforced and protected by the powers granted by law and custom to each area. The recommendations of the Commission, if adopted, will enable the catchment authorities appropriately to modify the constitutions of these areas. Further, the upland districts, the drainage water of which increases the difficulties of dealing with the lowland areas, will be under their jurisdiction.

It is asserted that the drainage of upland agricultural districts by pipe and mole drains has shortened the time taken for this surplus water to reach the main stream. As a result, flood water that formerly slowly percolated by undefined channels is now discharged much more rapidly, and has forced the lowlander to increase his embankment protections and to enlarge the outfall facilities of the main stream.

The claim is undoubtedly correct; large areas were drained in the middle of last century, and except where drains were laid too deep to be of service, the condition of the land was improved. Renewed attention is now being paid to field drainage, and we hope it will be examined not only as a simple technical question of removing surplus water, but also as one of the related aspects of soil physics demanding fuller investigations in the light of recent advances in the theory and practice of this subject.

It is indeed questionable whether drainage alone is the best method of dealing with occasional surplus water. In spite of our adequate and well-distributed rainfall, foreign agriculturists visiting Great

Britain are surprised at the susceptibility of our crops even to mild droughts; the suggestion is frequently made that our normal cultivation operations do not conserve sufficient soil moisture. The principles underlying these operations are certainly worthy of further study; they reached their present form about 1750, and were based on cheap labour and on horse power. Greatly increased labour costs have altered the situation completely, but the cultivation methods have not undergone any essential modifications to meet the new conditions, in spite of the facilities for mechanical power now available. A full examination of the effects of deeper cultivations, subsoiling, and rotary tillage on the amounts and rate of flow of percolation water, and studies of the influence of mulching on evaporation, should give valuable information on the ability of the soil to hold a greater reserve moisture supply. These problems are essentially physical, and they imply parallel studies of the physical and physico-chemical properties of the finest soil particles, the colloidal nature of which makes the soil differ in many respects from a simple porous material.

There is another aspect of the subject. This fine material is now known to exercise a controlling influence on both the inherent fertility of the soil and its ability to fall into that favourable physical condition known as good tilth. Unfortunately, this material is the most susceptible to removal by erosion and drainage to lower levels, where it silts up and intensifies outfall difficulties. In areas where it can be accumulated, it gives rise, as would be expected, to a very fertile soil. The narrow belt bordering the Nile, the warp-lands of the Humber estuary, and to some extent the polders of Holland, are well-known examples where natural forces or man's intervention have succeeded in saving some of this valuable material for agriculture.

Finally, we may point out that the above problems of drainage, tilth, and fertility are combined with peculiar force in all irrigation areas, and it is encouraging to note that those members of the recent Imperial Agricultural Research Conference most familiar with the practical problems of overseas agriculture were foremost in urging the vital necessity of fundamental research on the soil. The establishment of a Bureau of Soil Science, as suggested at the Conference, would be a distinct aid to such research by collating the results and showing the bearing which soil survey work has on problems of drainage and of irrigation in all parts of the Empire.

The Dolomites of South Tyrol.

Das Grödener-, Fassa- und Enneberggebiet in den Südtiroler Dolomiten: Geologische Beschreibung mit besonderer Berücksichtigung der Überschiebungserscheinungen. Von Dr. Maria M. Ogilvie Gordon. 1 und 2 Teil: *Stratigraphie-Tektonik.* (Abhandlungen der Geologischen Bundesanstalt, Band 24, Heft 1.) Pp. xxiii + 376 + 26 Tafeln. 90*s*. 3 Teil: *Paläontologie.* Mit einem Atlas von 13 Tafeln. (Abhandlungen der Geologischen Bundesanstalt, Band 24, Heft 2.) Pp. 89. 30*s*. (Wien: Geologische Bundesanstalt, 1927.)

THE work under review is one exceptional for its comprehensiveness, and one that marks the conclusion of an enormous amount of labour both physical and mental, on the part of the author, Dr. Maria Ogilvie Gordon. Begun in youth, under the ægis of two great students, Ferdinand von Richthofen and August Rothpletz, both long since dead, it was completed after she had borne with fortitude the bitter blow that fate had dealt her as a wife, and after she had devoted her energies to her country's cause during the War. By reason of the length of the period over which the work was spread, and the magnitude of the events that encompassed us all during the years of interruption, her earliest work must appear now as objective to her as to the reviewer. It must almost seem not to be her own work, but that of some stranger of a past generation. Yet underlying all her work, from those early days of 1893 up to the present time, one motive may be traced—the endeavour to unravel the tectonic structure of the Dolomites, enormously complicated in reality, albeit described as simple by some; and, on the basis of this work, to solve certain other problems, one of the most important of which is the question, first raised by von Richthofen, and since repeatedly denied or affirmed, as to the coral-reef origin of the gigantic masses of limestone and dolomite. It must, moreover, be mentioned with approbation that the author, in spite of the keenness and originality of her own perception, has adhered to the principle laid down by von Richthofen so to present her observations that they remain available for other interpretations. This remark is especially applicable to the work now under review.

The volume comprises an almost overpowering wealth of detailed observations concerning the stratigraphy, the tectonics, and the palæontology of the area studied. Nobody will ever think of starting work upon this area without availing himself of this colossal archive of observations, while he who also knows the actual mountaineering difficulties that face the worker in the Dolomites cannot but express his wonder at the energy, the courage, and the spirit of the author.

The first section of the work, consisting of 169 large quarto pages, is devoted to stratigraphy. It begins with a comparatively short description of the Permian (Bellerophon limestone and quartz-porphyry). The several stages of the Trias are, on the other hand, most exhaustively portrayed. The old division of the Werfen beds into a lower series (Seis beds) and an upper series (Campil beds) is retained, but the conglomerate of Richthofen is referred to the Lower Muschelkalk, so that, in this respect, the classification differs from that of Wittenburg. Numerous detailed profiles are given, both for the strata of this series and for those of higher horizons.

In the Upper Anisian stage the occurrence of *Diplopora annulatissima* Pia at numerous localities is described. The Lower Buchenstein beds of Mojsisovics are here included. The Buchenstein beds *sensu stricto* (*Protrachyceras reitzi* and *P. longobardicum* zones) and the Wengen beds (*P. archelaus* zone) are grouped together as the Ladinian stage. The eruptive rocks of this age receive very exhaustive treatment. The author concludes from her observations that, during the period of deposition of the Upper Buchenstein beds, differential movements of the earth's crust occurred along the northern margin of an anticlinal flexure or elevated zone with a W.N.W.-E.S.E. trend, while erosion and re-deposition of the limestone and dolomite sediments occurred. Lavas and tuffs were erupted from the fissures that were developed in the sunken northern section. This process did not occur continuously, but at intervals. Hence along the border zone between the two facies the volcanic rocks sometimes predominated, and sometimes the limestones and dolomites. This is the true reason for the extremely complicated differences in facies met with in the area.

During the period of the Wengen beds, the eruptive activity decreased only slightly, eruption taking place along the same structural lines as during the Buchenstein period. Both for this and for palæontological reasons, the author unites the Wengen with the Buchenstein beds, and separates from them the so-called Pachycardia tuffs.

The St. Cassian and Raibl beds are grouped together as Carnian, since the author has been able to show, in the so-called Upper St. Cassian beds, the close connexion between the horizons above and below, thereby demonstrating the absence of any gap in the history of the marine faunas. In the Raibl beds also a very sudden change in facies is demonstrated. Each subdivision of that series of strata can be shown to pass laterally from a calcareous or sandy facies into dolomite.

Next follows a section bringing together all the available information bearing on the coral-reef theory. The author is in favour of the view, developed by the present reviewer, that the chief builders of the great calcareous masses were not corals but calcareous algæ. She proves conclusively that the reef-like appearance of many of the present-day dolomite mountains is due primarily to later tectonic movements, even if it has depended also on facies differences.

The tectonics are dealt with in a most thorough manner. This section of the work is made all the clearer by the inclusion of a map on the scale of 1 : 100,000, showing the tectonic lines, two large charts of profiles, a geological map of the Enneberg district on the scale of 1 : 25,000, a geological map of the Schlern district (1 : 25,000), including, to the north, the Gröden Valley, and to the south-east the upper portion of the Fassa Valley as far as the western slopes of the Marmolata, and a small map of the Rodella district (1 : 12,500), with two special profiles.

In the space of a short review it is impossible to deal in full with the author's interesting and detailed observations. The most important result is the demonstration of the existence of two series of tectonic movements; these occurred at different periods and acted in different directions. The older had a general W.N.W. trend, the younger an N.N.E. trend. The result was a sort of interference, and a tendency to produce a turning movement of mountain masses. For this turning movement the author uses the term 'torsion.' Many might deny the propriety of this use of the term. To the reviewer the actual term used seems to matter less than the facts observed; and there appears to him to be no doubt that the statements of Dr. Gordon in this connexion are trustworthy and deserving of the greatest respect, even if one differs in their interpretation.

Overthrusting also was connected with this phase of earth movements, and on this subject the present work contains a mass of important observations. It is true that this overthrusting was not on the same scale as that of the large Alpine nappes. Nevertheless, it is not to be underestimated, as Cacciamali's studies in the Alps of Lombardy have also taught us.

The author has rendered especial service by the clear manner in which she has described the tectonic rifts to which the considerable volcanic activity of Triassic times was due.

In the palæontological volume, a large number of known fossil species as well as a few new forms are figured on thirteen plates and carefully described in the text. The new species are *Allorisma depressa*, *Avicula stachii*, *Gymnocodium nodosum*, *Pecten nicolensis*, *Myophoria elliptica*, *Leda minuta*, *Thecosmilia norica*, *Elysastræa parvula*, and *Milleporidium fassani*. The chief importance of this section lies in the fact that the horizons of the fossils are accurately determined, while new localities and horizons are recorded for various algæ and hydrozoa, and investigations are made into the structure of these organisms. The author has found in the Bellerophon limestone at various localities the algæ *Mizzia velebitana* and *M. yabei*, hitherto known only from the Upper Carboniferous of Dalmatia and Japan, as well as *Vermiporella velebitana*.

The whole work is sumptuously got up and excellently illustrated. It is a credit to the Vienna Bundesanstalt. Together with the earlier works of the author it forms a monument in the field of Alpine geology upon which both special and general geologists, professional or not, may look with pride and satisfaction.

WILHELM SALOMON-CALVI.[1]

Biology before Darwin.

(1) *De Linné à Jussieu : Méthodes de la classification et idée de série en botanique et en zoologie* (1740–1790). Par Dr. Henri Daudin. (Études d'histoire des sciences naturelles, 1.) Pp. v + 264. (Paris : Félix Alcan, n.d.) 20 francs.

(2) *Cuvier et Lamarck : Les classes zoologiques et l'idée de série animale* (1790–1830). Par Dr. Henri Daudin. (Études d'histoire des sciences naturelles, 2.) 2 vols. Vol. 1. Pp. xvii + 460. Vol. 2. Pp. 338. (Paris : Félix Alcan, 1926.) 60 francs.

WE are not familiar with the name of Dr. Henri Daudin, of Bordeaux, as a working biologist, but however that may be, he has, in the above treatise, produced a history of modern biology which it would be inexcusable to overlook. His original intention was to discuss the historical aspects of the works of Darwin and the evolutionary school, but he has instead traced the development of systematic biology during the immediate pre-evolutionary period, and has hence preferred to devote his attention to causes rather than to effects.

Dr. Daudin divides his work into two sections, the first of which deals with the years 1740–1790, which he regards as introductory to his main or critical period extending from the latter date to 1830. There is something to be said for this division. The years in the neighbourhood of 1790 were certainly critical. They stand at the onset of that sudden burst of research activity which culminated in the 'thirties and thence rapidly declined. Thus Dr. Daudin's final date is also a significant one. On the other hand, to stop at 1830 results in including the early and less productive years of a large number of distinguished workers, ranging back from Stannius and Michael Sars to Dufour. It would have been more logical and instructive to have extended the limit to 1840, or at least to 1835, so as to include the first years of the decline.

Before 1790, research was neither intensive nor coherent. The old school, including O. F. Müller, Spallanzani, the Hunters, Meckel, Camper, Bonnet, Daubenton, Ellis, Lyonet, Buffon, and Linnæus, representing all the earlier phases of descriptive and speculative biology, was slowly preparing the way for the emergence of Cuvier, whose work covers the whole of the very important period from 1790 to 1830, of which it may be said to constitute the foundation. It is not easy to explain fully the sudden display of activity at the beginning of Cuvierian times. The publications of Buffon, and to a lesser extent those of Bonnet and Spallanzani, had aroused a definite and widespread interest in the investigation of animals, and must have exerted some influence on the extent and trend of contemporary inquiry. Dr. Daudin's earlier date of 1740 may be justified as a more or less natural boundary between the methods and traditions of the seventeenth century and those of the pre-Cuvierian school.

The works under review embrace a prolific period, the adequate investigation of which involves the examination of piles of literature. This has naturally occupied the leisure of the author for many years, and the result is a serious contribution to the subject based on original authorities. There are, however, several omissions within the limits Dr. Daudin has laid down for himself, and some of them are of first-rate importance. Indeed the author almost confines himself to the work of the French school, which is fully and carefully debated, but no history of the period can be said to be in any sense complete which omits discussion of the publications of Roesel, Meckel, Hunter, Spallanzani, the second Monro, Bojanus, and Straus—to mention only a few of the more important names. A further criticism of the author's bibliographical methods is that wrong editions are frequently quoted, and translations are used instead of the originals. Contemporary translations are helpful as evidence of how an author was interpreted in his own time; but they are often misleading, and it is never safe to assume that the translation accurately conveys the meaning of the original text. We have, on the contrary, at times encountered wide differences between the two. It is necessary, however, to make allowances for a writer in the provinces, far removed from the National Library—probably almost the only French library which could provide him with all the literature he needed.

---

[1] Translated by L. R. Cox.

The history of animal classification before Darwin receives special and admirable treatment in these volumes. Dr. Daudin attaches considerable importance, and rightly so, to this aspect of the subject, because the constant striving after an acceptable classification must sooner or later lead to a natural classification, or in other words to the recognition of evolution. The only guarantee of the reality of a group is that its members should constitute a harmonious whole, with which members of other groups are out of tune. The intuition which introduced the word 'family' into pre-evolutionary classification carries with it a prophetic recognition of the doctrine of common descent.

The fact that the biological catalogues of the seventeenth century were already crystallising into natural groups before the time of Darwin can only be regarded as the unconscious growth of the idea of descent, and many pre-Darwinian naturalists must certainly be credited with this 'intellectual perception.' In the domain of morphology the recognition that, for example, the abomasum of the compound stomach is the only part homologous with the stomach of other mammals is a comparable result. Thus, as Daudin points out, the truth was in Lamarck even before he became a conscious transformist. The steady and unobtrusive work on classification and comparative anatomy did more to precipitate the coming of evolution than all the brazy rhetoric of the so-called philosophers of the Geoffroy school—"plus hardis que solidement informés."

We may be permitted to regret that historians of science are not occasionally tempted to apply the knowledge which they so laboriously acquire. Who better than the historian could tackle the epidemics of callow speculation which afflict us from time to time, and check the exuberance and tyranny of the latest fashion in research. We are called upon to accept, on pain of excommunication, creeds and dogmas which we regard with vigorous misgivings. The modern speculator excuses his vice on the ground that it is better to have a bad theory than no theory at all. History not only gives little support to this ingenuous claim, but even cries out aloud against it. An unsound hypothesis, should it gain general acceptance, hangs like a millstone round the necks of contemporary workers. It is easy to show that a doctrine like the preformation theory in embryology, or the vertebral theory of the skull, not only retards the advance of science, but also may cruelly oppress a sound observer who has the genius to see through its absurdities and the courage to expose them.

Progress in science is the result of faithful observation combined with the generalisations of those rare individuals who are born to this difficult task. The historian can smile at the modern worker who holds the speculations of Oken and Geoffroy in contempt, but lacks the imagination to suspect that a future generation may be mildly amused at his own magnificent system. On matters such as this the historian should have much wholesome and weighty advice to offer. Why does he not produce it ?

The Validity of Modern Physics.

The Logic of Modern Physics. By Prof. P. W. Bridgman. Pp. xiv + 228. (New York: The Macmillan Co., 1927.) 10*s*. 6*d*. net.

THE author of the latest discussion of the foundations of physics, Prof. P. W. Bridgman, of Harvard University, is a highly distinguished experimenter in a branch of physics with a peculiarly difficult technique, most of which he has developed himself, while his experimental work has repeatedly been greatly aided by his capacity for doing his own incidental theory. His main attitude in the present work may be called a qualified phenomenalism; that is, apart from the material objects of ordinary observation, he is prepared to admit other concepts, but anxious to keep their number down to a minimum. His est of the validity of a concept is that the old acts co-ordinated must outnumber the new assumptions made. The fundamental analysis in erms of sensations is not attempted, but the view s consistently maintained that a physical magnitude is defined by the operations that measure it and not by any prior considerations. The opening discussion of the meaning of length, in application to atomic and electronic distances on one hand, and stellar distances on the other, where the ordinary methods based on measuring scales are useless for opposite reasons, brings out extremely well the nature of the logical problems involved. On this point of view it is simply meaningless to assert or deny a physical proposition without some means of verifying it experimentally; thus the statement that space on a small scale is Euclidean is meaningless.

The rejection of unobservable entities until he is forced to accept them leads Bridgman to accept action at a distance, and to reject the ether, while with the latter goes the physical reality of the electric field. But the point assumes a knowledge of what we mean by physical reality in this connexion. Bridgman seems to know what it means, and not to believe in it. So far as I can tell, the situation is that measurement of the forces on electric charges and magnetic poles gives the values of the electric and magnetic forces experimentally wherever we like to find them, and that these vectors satisfy Maxwell's differential equations. If the possibility of measurement is enough to determine physical reality, the electric field is as real as distance.

The notion of action at a distance, on the other hand, seems to mean that the field is determinate when we know the neighbouring charges and magnets, and is independent of the intervening medium. But actually it depends on the dielectric constant and permeability of this medium, which is therefore highly relevant. The reviewer's own point of view is that the differential form of the laws is more general and, except in the simplest cases, more fundamental in knowledge than the integrated form, and involves direct reference to intervening places. Consequently, while having no use for the ether, I should accept the field and reject action at a distance when they are defined so as to convey any meaning to me.

In a later part of the book Bridgman discusses problems of time and relativity. From his phenomenalist point of view he is led to reject the notion of light at any places except those where it is emitted or absorbed, because all means of testing its presence at intermediate places involve either diverting or destroying it. Thus light as a thing travelling with a finite velocity disappears. With it goes Einstein's definition of simultaneity; the velocity of light is made infinite by "setting a distant clock on zero at the instant it receives a light signal flashed from our clock at its zero." In this way we arrange for the light to spend no time on the way in going; but if we fix a mirror at the distant clock the light spends twice the accepted time on the way back, and the trouble about observing the returning beam is as acute as ever.

This seems to be a case where pure phenomenalism is impracticable. The phenomenalism of Mach and Karl Pearson was a reaction against the realist and mechanist attitude of the older physics, expressed especially in such concepts as absolute position and the elastic solid ether. Accepted physical laws had to be re-examined to find out how far they were demanded by the data; mere consistency with the data was no longer enough. The results were seen in improved understanding of essentials and attention to formal properties instead of models, and cleared the way for such positive advances as the theory of relativity and the modern quantum theory. But a critical attitude towards fundamentals does not mean that we must deny the existence of anything we cannot perceive directly. It is true that light cannot be perceived in transit; but if we therefore deny its existence we immediately get into worse difficulties.

The author gives a discussion of the value of mathematical methods, appreciating both the utility and the danger of their ability to carry us far beyond the original data. Later he gives an extended account of the validity of the postulate that physical laws are formally simple. He has thus given all the preliminaries to an analysis of the validity of physical laws in terms of probability, but he does not attempt such an analysis or mention what progress has been made by other writers.

Prof. Bridgman's points are always well made and his style is attractive. His acute, though at times too far-reaching criticism is the best example known to the reviewer of both the benefits and the drawbacks of the phenomenalist attitude, and his work can be strongly recommended to the attention of those interested in the foundations of science.

HAROLD JEFFREYS.

Our Bookshelf.

Meteorological Office: Air Ministry. British Rainfall, 1926: the Sixty-sixth Annual Volume of the British Rainfall Organisation. Report on the Distribution of Rain in Space and Time over the British Isles during the Year 1926 as recorded by about 5000 Observers in Great Britain and Ireland. (M.O. 295.) Issued by the Authority of the Meteorological Committee. Pp. xv + 293. (London: H.M. Stationery Office, 1927.) 15s. net.

THE sixty-sixth volume of "British Rainfall," which deals with the year 1926, follows the lines of earlier volumes and is mainly statistical. There are tables and diagrams giving the total rainfall in each month, and for the whole year. The monthly totals are for nearly four hundred stations evenly distributed over the British Isles, while the annual totals are for nearly five thousand stations. The monthly evaporation from a free water surface, and the amount of rain percolating through depths of twenty, forty, and sixty inches of soil, in relation to the rainfall of each month, appear for a dozen stations. Covering as they do a variety of soils, these figures provide information of considerable horticultural interest. The annual rainfall statistics, on the other hand, continue to constitute indispensable information for engineering firms dealing with water-supply. An interesting analysis of heavy falls of rain in short periods is given (pp. 44-54). It includes figures for 1926 as well as for previous years. Falls of an inch in ten minutes have apparently occurred on several occasions, though not in 1926, and there is one instance of a quarter of an inch descending in a minute and a half.

To the general student of meteorology, mere statistics, especially when they refer to one meteorological element only, are of limited interest, and for this reason analyses of individual occasions of exceptional rain, illustrated by synoptic charts, such as are given for the severe and widespread thunderstorms of July 17–18, and for the heavy cyclonic rains of Nov. 4–5, are welcome additions.

It is interesting to note that for the British Isles as a whole, 1926 was rather a wet year, and was the fifth in succession to have a total equal to or greater than the average—the longest run of wet years experienced since 1875–83. The year 1927, it may be observed, will be an addition to this run. In distribution the rainfall of 1926 was very erratic, including the wettest January since 1877, the wettest November since 1870, and the driest December since 1870, when comparable statistics first became available.

How we Behave: an Introduction to Psychology. By Prof. A. E. Heath. Pp. vi + 90. (London: Longmans, Green and Co., Ltd., 1927.) Cloth, *2s.*; paper, *1s.*

AMIDST the mass of psychological works that emanate from the printing presses at the present time, this little book deserves more than a passing notice. It is one of an admirable series designed, in the words of the prospectus, "to meet a wide spread demand from working-class students fo inexpensive introductory books on subjects studie in elementary classes," and published under th auspices of the Workers' Educational Association. The present work fully keeps up the higl standard set by others in the series. It is, indeed remarkable with what success Prof. Heath ha tackled the task, that one would have been incline to pronounce impossible, of giving an adequat introduction to psychology within the limits o ninety small pages. It is of course intended as a introduction and not a complete survey of th subject, and it is a merit of the work that it constantly suggests further questions in a way whic cannot fail to stimulate the student to carry o his inquiries. The general scope of the work i sufficiently indicated by the chapter headings "The Nature and Aim of Psychology," "Th Subject Matter of Psychology," "The Development of Animal Behaviour," "The Development o Human Behaviour, (1) Towards a more Unified Response of the Self as a Whole, (2) Toward Completer Adjustment to the Full Realities of th Environment."

Prof. Heath studies the working of the min from a dynamic point of view, and emphasises th element of conation or 'striving' in mental life If he ever expands what he has to say here into a fuller work, one would welcome more detaile discussion of the relation of this 'striving' t consciousness, a point on which, while interestin and suggestive, he does not seem perfectly explicit. The only general criticism, if it is a criticism, that one could suggest, is that the student who begin on this work might get the impression that psychology is always a delightfully interesting and amusing study, a dream from which he would be likel to have a rude awakening when he went on to th works of some other authors. G. C. FIELD.

Fūrie Kyūsū oyobi Sekibun Ron, being a Japanese translation of H. S. Carslaw's "Introduction to the Theory of Fourier's Series and Integrals." Translated by G. Takemae. Pp. xii + 482. (Tōkyō: Uchida Rōkakuho, 1927.) 8 yen.

DURING the last fifteen years or so, several important books on physics and mathematics have been translated into Japanese. To the list of these is now added the book under notice. It is translated with accuracy into a clear and simple Japanese. In the preface the translator describes the difficulties which he had to cope with in bringing the book to the stage of publication, occasioned by the great earthquake of 1922 and his long illness in following years. Both the translator and the publishers must indeed be congratulated on their admirable work in translating and publishing in such a clear and well-printed form this excellent book by Prof. Carslaw.

The translation will no doubt prove useful to Japanese students of physico-mathematical and technological science. One fears, however, that the translator may not receive due reward for his labours. All Japanese university science students are able to read English well enough to understand the explanations of a technical book, and it is unnecessary for them to resort to translations. Especially is it so with a book on mathematics. Moreover, the reading of foreign books in the languages of the originals is to be encouraged, as later on it will be necessary for many of them to read original papers in foreign languages as well as in Japanese.

Nevertheless, the present translation will be very welcome to students who cannot go through a systematic course of study, either of their special subject or of the language in which that special subject is written. Furthermore, in the present translation are included various important alterations and corrections due to Prof. Carslaw, thus rendering the translation more up-to-date than the original work. S. YOSHITAKE.

The Magneto Manual. By H. R. Langman. (Lockwood's Manuals.) Pp. x + 221. (London: Crosby Lockwood and Son, 1927.) 7*s*. 6*d*. net.

IN practically every motor-car the ignition of the explosive mixture is effected by means of an electric spark produced by a small generating device called a magneto. During recent years considerable advances have been made in the design of these generators, and they are now thoroughly trustworthy. It is advisable, however, that every driver of a car should have some knowledge of the timing and setting of magnetos and of their necessary adjustments. He will find much that is useful to him in this book. Luckily, the permanent magnets of magnetos now normally retain their magnetic properties for many years. This is due mainly to the great advances that have been made in the manufacture of magnetic steels and to improved methods of magnetising them.

Heat and vibration, however, have a demagnetising effect even on the best magnets. It sometimes happens, therefore, that the magnet becomes weak and the functioning of the device becomes uncertain. The pull of the magnet can be easily tested by placing a soft iron keeper across the poles and by means of a spring balance measuring the pull required to displace it. A good-sized magnet when new can easily support a weight of at least sixteen pounds. The author gives some useful and convenient methods of testing and remagnetising the particular type of magnetos used in Ford cars, many of which are running in Great Britain. A list of questions is given at the end of the book, and this will enable the student to test his knowledge.

Land Tenure and Agricultural Production in the Tropics (being a Discussion on the Influence of the Land Policy on Development in Tropical Countries). By Dr. H. Martin Leake. Pp. ix + 139. (Cambridge: W. Heffer and Sons, Ltd., 1927.) 7*s*. 6*d*. net.

DR. LEAKE has had practical experience of tropical agriculture as Director of Agriculture in India and as Principal of the Imperial College of Tropical Agriculture in Trinidad. In discussing these vital problems, therefore, he has a first-hand knowledge of the facts in certain areas. It must not be thought, however, that he takes a restricted view of the subject, and while he recognises the importance of local knowledge of conditions, and has been at pains to make himself acquainted with these conditions, he argues on lines which aim at elucidating general principles modifiable in their application to specific cases.

How far Dr. Leake has been successful may perhaps best be judged from his very valuable and suggestive appendix on land tenure in tropical Africa, which is reprinted from the *Empire Cotton Growing Review.* He there suggests a triple partnership which would seem to merit a trial, though the position which is assigned to the chief is perhaps open to question. It is also doubtful how far it would be generally applicable even in East Africa, where it would seem best adapted to conditions among certain tribes only. With Dr. Leake's plea for increased agricultural education, his readers will find themselves in hearty agreement.

Psychology and the Soldier. By F. C. Bartlett. Pp. viii + 224. (Cambridge: At the University Press, 1927.) 7*s*. 6*d*. net.

IT is a difficult matter to discuss the practical application of psychology in a manner that appeals to the novice without offending the expert, but in this book Mr. Bartlett has succeeded admirably. Although he addresses himself primarily to the student of military affairs, his discussion is also of interest to the general reader. Problems of mental and physical fitness, tests for general ability and for special aptitudes, the effects of practice, the study of fatigue, and allied topics, are discussed simply and with appropriate illustrative detail. The sections dealing with leadership, discipline, and morale, and with the mental disorders of warfare, are, however, more attractive because more expressive of the author himself. Such a combination of sound psychology and simple exposition deserves a larger audience than the students to whom it was originally addressed.

An Introduction to Psychology. By Prof. John J. B. Morgan and Prof. A. R. Gilliland. Pp. xi + 319. (New York: The Macmillan Co., 1927.) 7*s*. net.

THE suggestion that courses in elementary psychology to high school pupils will be of value is decidedly novel, but, when we consider the character of American high schools, not so ill-advised as might at first sight appear. In this text-book the authors have aimed at giving concrete expression to the idea. The work has been efficiently done and the book will doubtless meet the needs of those who require a formal text for class purposes. Interest in the 'parlour tricks' of experimental psychology is of course easily secured, and the authors have not overlooked this. The usual topics, such as the nervous system, habit, sensations, attention, learning, memory, etc., are included, but the treatment is very simple and is concerned chiefly with facts. Questions and references are given at the end of each chapter.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Pleochroic Haloes and the Age of the Earth.[1]

IN several communications, including one in NATURE (vol. 109, p. 480, 1922), Joly has directed attention to discrepancies between the position of the innermost ring of pleochroic haloes due to uranium and the accepted ionisation curve of the α-particles of uranium. Since the range of the α-particles which produce the haloes by ionisation processes is related to the velocity of decay of the disintegrating substance by Geiger and Nuttall's law, Joly concludes that uranium may have disintegrated more rapidly at one time than it does to-day, or that in early geological times a more rapidly disintegrating uranium isotope may have existed, the ionisation curve of which is no longer accessible to observation, owing to the fact that the isotope has decayed completely in the later geological epochs.

Objections to these conclusions have been raised, particularly by O. Hahn in his book "Was lehrt uns die Radioaktivität über die Geschichte der Erde?" (Berlin, 1926, pp. 55-56). Hahn assumes that the position of the innermost uranium ring is by no means anomalous, but that it indicates the true current range of the α-particles. From this it follows, of course, that the Geiger-Nuttall relation no longer holds valid for extremely long half-value periods.

Since no similar discrepancies are observed in the case of thorium haloes, Hahn's explanation raises difficulties, which can, however, be avoided if we assume the following causes to be operative in the production of the anomalies.

The range of an α-particle depends not only on the velocity of disintegration of the radioactive substance, but also on the physical constants of the medium into which the α-particle penetrates. Changes in the cohesion properties of the medium can call forth deviations in the range, without the intervention of accompanying changes in the rate of disintegration. Mügge's observations show that radioactive disintegration can produce isotropy in minerals, loosening of the crystal lattice, and alterations in cohesion (*Nachrichten der Gesellschaft der Wissenschaften*, Göttingen, 1922, Math.-Phys. Klasse, p. 110). Such processes must also take place within pleochroic haloes, particularly in the central portion, where for geometrical reasons the action of the α-particles is concentrated. In the region of the innermost uranium ring the effect must be particularly strong, for in this zone the α-ray absorption shows a maximum value, as is indicated by the integral ionisation curve of uranium, which possesses a steep peak in this position.

We must, therefore, conclude that the coloration of the mineral is accompanied by an alteration in its cohesion properties, with a corresponding increase in the range of the α-particles. This increase will be revealed especially in the *innermost* uranium ring; it will probably remain outside the limits of measurement for the remaining rings. On the basis of this assumption, the history of a uranium halo will be somewhat as follows:

The innermost ring first develops at the normal distance from the nuclear inclusion. With advancing development, and corresponding to the increased range, the outer periphery of the halo advances in a radial direction, whereby the part of the ring directed towards the centre is no longer darkened to the same extent as previously and soon is lost in the general brown coloration of the inner parts of the halo. The outer radius of the innermost halo thus increases in the course of time, exactly as in Joly's observations. The changes in cohesion which it is necessary to assume to explain these alterations of the radii are but very small.

That an analogous phenomenon has not hitherto been found with thorium haloes is, in my opinion, due to the fact that the integral ionisation curve of thorium is not so steep as that for uranium, but is much more evenly distributed. In particular, no marked maximum of absorption of the α-rays coincides with the innermost rings, as in the case of uranium. Changes in the cohesion properties of the mineral containing the halo are thus smaller, and above all more uniform, for thorium haloes than for uranium haloes. Corresponding anomalies in the radii of the haloes are therefore much more difficult to detect. In the elucidation of this question, however, it is very desirable that accurate observations in this matter should be carried out, and that in this connexion attention should be directed to a possible dependence of the position of the innermost halo on the physical and chemical nature or condition of the containing medium.

The explanation I have given of the anomalies in the uranium haloes invalidates Joly's assumption of the existence of uranium isotopes with abnormally high disintegration rates in early geological time, and hence the conclusions as to the calculation of geological ages which Joly has drawn from this work appear unjustified.

The Nature and Function of Golgi Bodies.

"Youth is, we all know, somewhat reckless in assertion, and when we are juvenile and curly, we take a pride in sarcasm and invective."—BENJAMIN DISRAELI.

THE opening sentence of Prof. Gatenby's letter (NATURE, Jan. 7, pp. 11 and 12) raised in me hope that at last we should be given some kind of indication of the function of the Golgi bodies, by one who has apparently devoted himself to them entirely. On reading through his letter I find that he makes no suggestion as to function, and that the only definite destiny attributed to them is that they form the acrosome of the sperm. As, however, we are also told that the Golgi bodies are "as universal as the nucleus itself" in animal cells, this cannot be their only destiny; and as this assertion claims no more than that the Golgi bodies give rise to a specific structure in a particular group of highly specialised cells, which in a certain sense can scarcely be regarded as part of the body of the animal or plant, we are still left in ignorance as to what Prof. Gatenby believes is the function and destiny generally, of what he calls "this intra-cellular organella."

I suppose that the most modest of men would not, in ordinary circumstances, be displeased if he were told that he had had part in a scientific discovery. Prof. Gatenby's style is such that when he writes, "It was really Moore and Walker who discovered the 'Golgi apparatus' in animal spermatogenesis!" I am not sure whether he gives this as his own or someone else's opinion. In either event the opinion is mistaken, and the mistake does not please me. The particular vesicles described in the paper of which I was part author ("The Meiotic Process in Mammalia." Univ. Press, Liverpool, 1906) were described by Benda in 1896, by Baumgartner in 1902 and 1904, by others later, and again by me in 1925 (*Proc. Roy. Soc.*, B, vol. 98). Their behaviour under the action of staining and fixing reagents is entirely different from that attributed to Golgi bodies by Prof. Gatenby. In fact, when the methods he recommends for the demonstration of Golgi bodies are used, only a distorted image of the later stages can be traced, even by one familiar with these structures in properly preserved material.

---

[1] Translated by Dr. H. W. Lawson.

It is curious and suggestive that these vesicles, which can be traced through three cell generations, which are described as going to form the cap of the sperm, and are best demonstrated by those methods of fixation regarded as least likely to distort the structure of the cell long before Golgi bodies became fashionable, should be those which are now claimed as the Golgi bodies which can be seen in the living cell. The true Golgi body, according to Prof. Gatenby, is not demonstrable in fixed material if acetic acid is used, and the material requires subsequent treatment for a week or two in osmic acid, or the use of some other drastic method such as those, the use of which is deplored by many histologists, necessary in the case of some preparations of nervous tissues; deplored because, though they are requisite for the particular purpose in view, they distort the structures to be examined. I see no reason, therefore, for calling a structure which is best demonstrated by the use of a fixative containing a considerable percentage of acetic acid and by rigidly avoiding the methods recommended by Prof. Gatenby, a Golgi body; particularly as its history and destiny were more clearly shown by other investigators many years before he published his first paper upon the subject.

With regard to the rest of what Prof. Gatenby calls Golgi bodies, I am sorry that he did not give any reasons for his condemnation of my paper (*Proc. Roy. Soc.*, 101; 1927). His assertion that I have been asleep for thirty years I can scarcely regard as bearing upon the validity of my observations. Nor do I see that their truth is affected by my failure to quote papers by a botanist on "mitochondria *which even divided*."

The observations referred to were briefly as follows. If mixtures containing proteid, peptone, albumose lipins, and other substances found in cells, are treated with a fixative that does not contain acetic acid, structures indistinguishable from the 'Golgi bodies' may be demonstrated if the preparation is dealt with according to Prof. Gatenby's osmic acid method. Moreover, if minute globules of fat are introduced into the solutions, some of the 'Golgi bodies' take up 'a juxta-nuclear position' just as do some of the 'Golgi bodies' in the cell. They do not appear if the lipins are omitted from the mixture. If acetic acid is used in the fixative, the 'Golgi bodies' do not appear either in my mixtures or in the cells. Now all cells, animal and vegetable, contain lipins, chiefly lecithin and kephalin, therefore it would be very surprising if these bodies did not appear in the cells just as they do in the mixtures.

How are Prof. Gatenby's assertions supported? Evidently from his letter there is much disagreement even among the adherents of the Golgi body. But he quotes "the leading English workers" as believing certain things about them. Who are the leading English workers? Prof. Gatenby's style of writing again makes me doubtful as to his exact meaning, but I rather gather from his letter that he means himself, Dr. Ludford, Dr. Brambell, and Miss Shana King. Surely there are some others! But later on in his courteous criticism when he says, "If Prof. Bose expects other cytologists to accept the view . . . , he is much mistaken," he appears to consider himself justified in speaking for cytologists in general, so perhaps these really are our leaders.

There is one request I would venture to make of Prof. Gatenby, and that is that he would cease to use the word 'inclusions' in describing all structures contained in the cell or even in the cytoplasm. I hope he means something different from what the word may be interpreted as meaning when he uses it thus. The invention of a new word, or trying to give a new meaning to an old word, is always regrettable, though the former proceeding is sometimes unavoidable.

A Dark Space in High-frequency Discharges.

KIRCHNER (*Ann. d. Phys.*, 77, 287; 1925), Gill and Donalson (*Phil. Mag.*, 2, 129; 1925), and Wood and Loomis (NATURE, Oct. 8, 1927) have shown that a glow discharge can be produced in vacuum tubes at very low pressures, provided the exciting current has a frequency of the order of 4×10^7.

Some experiments were carried out by me in which a 17 cm. spherical bulb, fitted with both internal and external electrodes, was excited at low pressures by a short-wave oscillation generator having a frequency of $3 \cdot 8 \times 10^7$. Discharges of about equal brightness were obtained with either pair of electrodes.

When the internal electrodes (made of sheet aluminium 3 cm. × 3 cm.) were used, a well-defined dark space appeared surrounding each electrode. This dark space had the appearance of the well-known Crookes's dark space but differed decidedly in thickness. When the pressure was such that a 25,000-volt transformer produced a 12 cm. Crookes's dark space, this new dark space had a thickness of only 2 cm. The thickness of this new dark space proved to be more or less inversely proportional to the pressure, for on decreasing the pressure, the thickness increased to about 3·5 cm. At the minimum pressure used, the transformer produced no trace of a discharge in the tube. The dark space could also be seen when the tube was excited by means of the external electrodes.

According to Kirchner, the high-frequency discharge results from a to-and-fro motion of electrons in the rapidly alternating field, the distance between electrodes necessarily being greater than the amplitude of the to-and-fro motion of the electrons. On this hypothesis a dark region near the electrodes is to be expected, for if the mean position of the electron is less than half its amplitude of oscillation from an electrode, the electron will be removed from the field by the electrode. To account for the sharp boundary of the dark space, one must recall that the strength of the electric field in these high-frequency discharges is not large, so that only in the vicinity of its mean position will the electron have sufficient energy to excite radiation. It is probable that the change with pressure is due to an increase in potential, for lowering the pressure decreases the number of available electrons, and if we consider the to-and-fro motion of the electrons as a kind of displacement current, decreasing the number of electrons will change the potential across the tube.

Temperature and Salinity Observations in the Gulf of Aden.

MY letter on the observations of the outflow from the Red Sea, made by H.M. Surveying Ship *Ormonde* during the spring of 1927 (NATURE, Oct. 8, 1927, p. 512), and the account of the oceanographical work of the Italian Surveying Ship *Ammiraglio Magnaghi* in the same area during the spring of 1924 ("Camp. idrografica nel Mar Rosso della *R.N. Ammiraglio Magnaghi*, 1923, 1924." *Ricerche di oceanografia fisica*. Parts I. and IV.), were published independently and almost simultaneously. Prof. Vercelli has now sent me the drawing reproduced here (Fig. 1) with an expression of the hope that it might be possible to publish it also in NATURE.

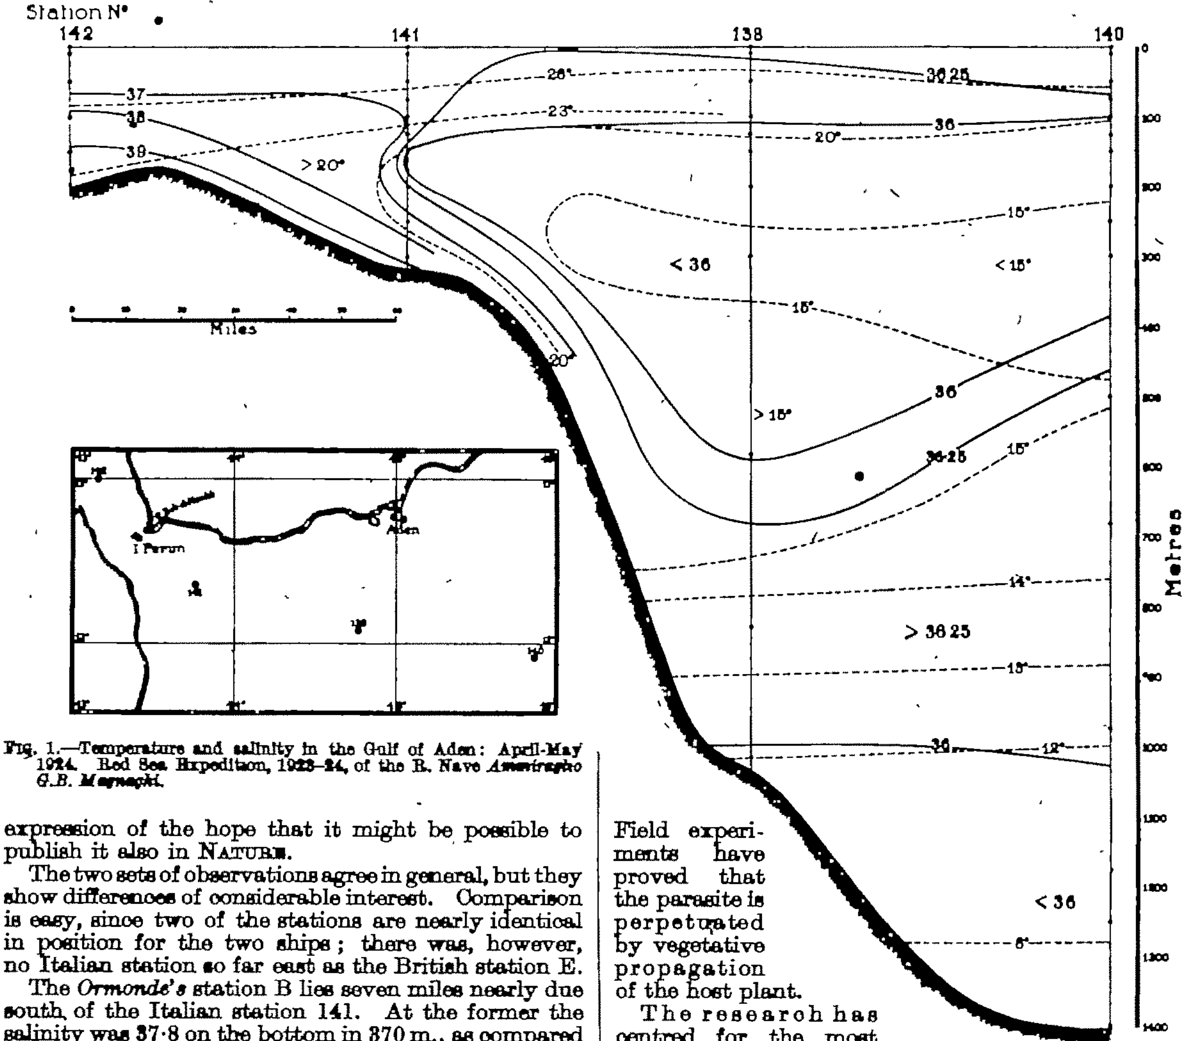

FIG. 1.—Temperature and salinity in the Gulf of Aden: April-May 1924. Red Sea Expedition, 1923–24, of the R. Nave *Ammiraglio G.B. Magnaghi*.

The two sets of observations agree in general, but they show differences of considerable interest. Comparison is easy, since two of the stations are nearly identical in position for the two ships; there was, however, no Italian station so far east as the British station E.

The *Ormonde's* station B lies seven miles nearly due south of the Italian station 141. At the former the salinity was 37·8 on the bottom in 370 m., as compared with 38·8 in the smaller depth of 300 m. at 141. Again, at D the *Ormonde's* maximum salinity was 37·54, at 1000 m., against 36·44 at 830 m. at the Italian station 138, which lies two miles farther northward and ten miles to the westward. The *Ormonde* sounded 1300 m. here, with water of a decidedly oceanic character, 35·76 salinity, at 1200 m.; the *Ammiraglio Magnaghi* found only 1015 m., so it is possible that the distance between the two stations was more than ten miles.

The differences support Prof. Vercelli's contention that the tidal currents in the western part of the Gulf of Aden extend to great depths.

Disease of Grasses caused by *Epichloe typhina*.

THE Ascomycete fungus, *Epichloe typhina*, has been recorded on eight species of Gramineæ in the neighbourhood of Aberystwyth during the past seven years. Although not a parasite of general economic importance in the district, the fungus has been decidedly destructive at the Station, entailing the loss of some valuable breeding plants. An investigation relative to the biology of the fungus started in 1922 has given some interesting results.

Epichloe typhina is found to possess a slender intercellular mycelium, which permeates the stems and leaves of infected plants at all periods of the year. Field experiments have proved that the parasite is perpetuated by vegetative propagation of the host plant.

The research has centred for the most part in the disease on *Festuca rubra*, a species which first aroused the interest of the writer by showing the conidial stage on exserted panicles. In most grasses the fungus fills the spaces between successive leaves of the fertile shoot and holds the panicle a prisoner.

Seed collected from diseased specimens of *Festuca rubra* has produced consistently a high percentage of infected plants. Visible symptoms of attack, namely, the formation of conidia external to the host, were not developed until the second or third year of growth, but microscopic examination of seedlings revealed the characteristic mycelium at the growing point and in the leaves. Some plants which remained barren for three successive years also revealed mycelium in the vegetative organs.

Mycelium similar to that found in other parts of the plant has been traced in the floral organs and in the ripe seed. So far mycelium has not been absent from any seed examined from an infected plant.

The mycelium occurs as scattered strands in the paleo and pericarp, but it is most abundant immediately outside the aleurone layer and between the endosperm and the scutellun. The mycelium does not appear to penetrate the cells. It has been traced within the tissues of the embryo itself, and in the first leaf of seedlings grown from infected seed under aseptic conditions.

The cytological relationship of the host and parasite as revealed under the microscope does not betoken any decided parasitic tendency on the part of the fungus, but an examination of the seed produced by infected plants gave definite statistical evidence of the adverse influence of the parasite.

The invasion of *Festuca rubra* by *Epichloe typhina* and its transmission by the seed are of particular interest in comparison with the endotrophic fungus of the genus Lolium investigated by Freeman and by McLellan.[1] Certain points of difference, notably the intracellular mycelium of the Lolium fungus, and its more thorough invasion of the seed, make it unwise in the present state of knowledge to push the comparison too far. Another parallel might be drawn between the behaviour of *Epichloe typhina* and the mycorrhizal fungus of Calluna described by Rayner.[1]

A further point of interest arising out of the present studies is the discovery of a fungus, in the roots of *Dactylis glomerata*, *Alopecurus pratensis*, and *Festuca rubra*. The fungus has an intracellular mycelium of the Phycomycete type and resembles that recently described in the mycorrhiza of various plants including wheat, *Holcus mollis*, *Festuca ovina*, and the genus Lolium.[1] In my opinion this fungus has no genetic connexion with *Epichloe typhina*.

Activation of Hydrogen by Electric Discharge.

IN a recent paper, Mr. G. A. Elliott (*Trans. Faraday Soc.*, **23**, 60; 1927) describes experiments on active hydrogen in an ozoniser. The activation was determined as usual by leading the active hydrogen over solid sulphur (which was placed very near to the discharge tube).

A mechanism of activation is herewith proposed which does not need such hypothetical species as H_3 (see F. Paneth, etc., *Zeit. f. El. Ch.*, 33, 102; 1927) and only involves ions and electrons. If the stream of hydrogen leaving the discharge tube carries ions (H^+_2, H^+, or both) and electrons, due to the fact that they have not all recombined, then the electrons may readily combine with the sulphur atoms, because the latter have a decided affinity for electrons. Sir J. J. Thomson uses this idea to explain certain phenomena in the electrodeless discharge in gases (*Phil. Mag.* [7], **4**, 1153 and 1157; 1927). The next step in the ozoniser reaction is then a simple ionic combination (see S. C. Lind, "Chemical Effects of Alpha Particles and Electrons." Second edition, Jan. 1928, Chemical Catalog Co., New York) between H^+ and S^- with the resultant production of H_2S. With the sulphur placed close to the discharge it is very likely that it is under an electric field due to leakage, and it is not necessary then to regard a slow rate of recombination of gas ions as essential.

Oxfordshire Flowers and the Plot Memorial Windows.

IN NATURE of May 28, 1927, p. 798, in the excellent account of the unveiling of the Wren-Ashmole-Plot Memorial Windows at Oxford, it is said that "the surrounding wreath is of two Oxfordshire flowers which Plot was the first to recognise as new to the British flora"—*Viola palustris* and *Geranium dissectum*.

I have dealt with these in my Oxfordshire Flora (lxxvii) and quote Morison's remark upon the Viola. He says (*Pl. Hist. Un. Ox.*, iii. 475, 1680): "Detecta fuit a Jacobo Bobert decennio abhinc"; moreover, it is doubtless Parkinson's ("Theatrum," 755, 1640) *Viola rubra striata Eboracensis*. So, too, with *Geranium dissectum*, Morison does not give Plot, but Bobart as its discoverer. It was actually included in Thomas Johnson's "Catalogue of Kentish Plants," published in 1629. So that neither of the two plants selected to appear in the wreath were actually new to Britain.

Plot, however, did discover a new species of elm (*Ulmus Plotii* Dr.) as well as *Potentilla procumbens*, *Sagina apetala*, and *Eleocharis acicularis*, the two latter not very adaptable for depiction in a floral wreath. The viola, however, and geranium are both figured in his History.

Crick Road, Oxford.

Experimental Measurement of the Surface Tension of Solids.

IN previous publications I have shown that the surface tension of solids can be determined experimentally by methods which do not involve any hypothesis as to molecular structure. As there is evidence that the structure of rock salt is more complicated than it appears at first sight, I devised a method which enables the molecular forces to be determined in a direct way. The method is limited to a certain range of values and is not applicable when the substances used act on each other; I have determined the surface tension of glass and rock salt. Now I find that this method, described in the *Phil. Mag.*, June 1926 and Oct. 1927, suitably modified, can be also used for many other substances and some metals in particular. Thus it is possible to determine the surface tension of antimony, bismuth, lead, tin, aluminium, cadmium, and zinc. For metals with higher surface tension, certain adjustment of physical properties is still necessary, and this will be done in due course.

Rayner, entitled "Mycorrhiza, an Account of Non-pathogenic Infection by Fungi in Vascular Plants and Bryophytes," *New Phytologist Reprint*, No. 15, 1927. The references are too numerous to print here.

Light and Sight.

By Sir John Parsons, F.R.S.

An opportunity for exemplifying one aspect of the relationship between physics and physiology, namely, that of the physical stimulus to a sense organ and the physiological response, was afforded by the Tyndall Lectures upon "Light and Sight," delivered by me at the Royal Institution on Nov. 1, 8, and 15. John Tyndall, in addition to being a physicist, drifted into biology, and by his experiments on spontaneous generation may be regarded as a pioneer in bacteriology. He was also a philosopher. He himself expressed his indebtedness to three men—Carlyle, Emerson, and Fichte. "These three unscientific men," he said, "made me a practical scientific worker." His philosophy led him strongly to support the pioneers of the evolutionary theory—Darwin and Wallace, Herbert Spencer and Huxley. Specially strongly did he support that canon of scientific discipline which was so ably enunciated by Huxley and rather unfortunately branded by him with the contentious name, agnosticism. Here Tyndall was overshadowed by his great contemporaries, and the immense effect of his Belfast address is liable to be overlooked by the historians of science.

The essence of the agnostic creed was a judicial suspicion of authority and the cultivation of suspension of judgment in regard to matters which are not yet susceptible of rigorous scientific proof. It cannot be doubted that the rise of the theory of relativity and the deductions therefrom have led to a weakening of scientific discipline and a too facile acceptance of plausible speculations. A reversion to the stricter canon of Tyndall and Huxley would be beneficial to all branches of science, and not least to physics, where hypotheses as to atomic structure, the constitution and life history of the stars, etc., are asseverated as facts with all the adamantine validity of the laws of the Medes and Persians. As Sir Arthur Keith has recently said, "The unfortunate position is that in this world there are men who will not be satisfied with not knowing"—an ambiguous remark which, however, as meant, embodies a great truth.

Our consciousness of the world around us is derived from impressions conveyed to our sense organs, of which the most important for us are the organs of vision. The integrated results of our sensory impressions are perceptions, which thus originate in the absorption of energy in various forms by the sense organs and its transformation into physiological impulses which are conveyed by sensory nerves to the brain.

In considering the radiant energy emitted by sources of light, such as the sun and artificial illuminants, and its distribution throughout their spectra, it is interesting to note that the human eye has become specially adapted to sunlight, as shown by the fact that the brightest part of the spectrum, as seen by the light-adapted eye, coincides more or less accurately with the summit of the curve of radiant energy.

As Helmholtz long ago pointed out, the eye shows many defects as an optical instrument. The refracting surfaces are not accurately spherical they are not accurately centred on the optic axis; they are not completely homogeneous and therefore give rise to irregular astigmatism, or completely transparent; the cornea and lens are not free from spherical or from chromatic aberration. Hence Helmholtz's oft-repeated dictum that if an optician delivered so faulty an instrument it would be justifiable to return it to the maker. Even Homer sometimes nods, and it is regrettable that Helmholtz should have uttered so unjust a sarcasm. For the true criterion of the eye as an organ of vision is its biological utility, *i.e.* its capacity to fulfil its manifold functions in the interests of the individual and ultimately of the race. An instrument approximately a sphere of 11 mm. radius, which combines the advantages of being a camera with automatic adjustment from infinity to a distance of 3 or 4 inches and unparalleled range of sensitivity, an efficient photometer, colorimeter, kaleidoscope, stereoscope, and range-finder cannot be regarded as inefficient.

The criterion of visual acuity is the capacity to distinguish two points of light as separate, *i.e.* the *minimum separabile*. This depends on the resolving power of the eye and the fineness of grain of the screen upon which the image is formed, *i.e.* the neuroepithelium of the retina. Experimental observations showing a minimum visual angle of 40″ of arc coincide well with the mean diameter of the foveal cones, 3μ. But contour discrimination, with a minimum visual angle of 10″, or even binocularly of 2″ (Andersen and Weymouth), is much less easy to explain. As shown by Hartridge, the key to the problem is found in the *difference* of illumination which is perceptible to cone vision. It is a striking example of the law that all perception is perception of change.

It can be safely stated that there is no form of sensory discrimination which is so highly developed as that of contours; and it is noteworthy that it has been employed empirically by physicists in the vernier. When the vernier method is inapplicable, as in photometry, the error of experiment is greatly increased. It is well for physicists to remember that the accuracy of their measurements depends upon a biological foundation (see Nature, 110, 824; 1922).

The bearing of these facts on the physiology and psychology of reading elicits many interesting conclusions. The defects of the optical apparatus lead to diffusion images, and cause irradiation, whereby the image of a dark object is encroached upon by the surrounding white. Irradiation in print is largely counteracted by the use of serifs and by careful design of the letters and spaces. Thus, the interspace between round letters like *o* and *e* should be less than that between square letters. Moreover, the significant parts of letters are usually in the upper half, so that a line of print can be easily read if the lower halves of the letters are covered, but is illegible if the upper halves are covered.

The eye is not only automatically adjustable to distances, but also its sensitivity is automatically adjusted to the amount of light entering it. The sensitivity of the retina increases enormously in dark adaptation, and scotopic or twilight vision differs in many respects from photopic vision. Evidence derived from physiological and pathological observations supports the view that the rods are responsible for scotopic, the cones chiefly for photopic vision. This is the so-called duplicity theory. Thus, the rod-free area of the macula is night-blind, as was long ago discovered by astronomers, and it is generally held that the Purkinje phenomenon is absent at the fovea. Further, the rate at which the eyes become adapted to dim light varies somewhat in normal people, and there are diseased conditions in which it is very slow or almost absent. Such people are night-blind. They are practically incapacitated in dull lights, and cannot get about after dark. In one rare group the eyes appear to be otherwise normal and the disease is transmitted from one generation to another. The most famous and most extensive pedigree of any diseased condition is that of some congenitally night-blind people in the Montpellier district in the south of France. The pedigree was started by Cunier in 1838 and brought up-to-date in 1907 by Nettleship. It consists of ten generations of 2121 persons, 135 of whom were night-blind. Much commoner is the night-blindness associated with the disease of the retina called retinitis pigmentosa.

An interesting antithesis to night-blindness is found in the rare cases of congenital total colour-blindness. For the normal sighted the colourless grey spectrum of scotopic vision becomes suffused with all the colours of the rainbow as the intensity of the light is increased. For the totally colour-blind, although the brightness increases under these conditions, no colours are seen. Moreover, there is no shift of the maximum brightness from the green to the yellow region of the spectrum, such as occurs in the normal.

On the duplicity theory, the congenital night-blind may be regarded as having only cone vision, and the totally colour-blind only rod vision. There are, however, difficulties in accepting this simple explanation.

The discovery of the visual purple indicates forcibly that the first stage in the energetics of the retina is photo-chemical. It is associated with electrical changes of great complexity; and whereas Adrian has shown that the electrical changes in the optic nerve are in all respects like those in an ordinary nerve under excitation, the correlation of these changes with those of the more complex retina has yet to be elucidated.

Stimulation of the retina by an instantaneous flash of light elicits two facts—the persistence of the visual impression for an appreciable time beyond that of stimulation, and the recurrence of vision. The latter is due to the pulsatile nature of the sensory response. It accounts for such peculiar phenomena as 'Bidwell's ghost,' Charpentier's bands, and so on. One of the most striking phenomena is the production of a colour sensation by pure black and white stimulation, as in Benham's top; and this has recently been partially explained by Piéron on the same principle.

The relations of these scientific observations on light and sight to such practical problems as the illuminations of rooms, factories, art galleries, etc., and the hygiene of vision in relation to flickering lights, the cinema, etc., is full of interest, but also often very obscure. The investigation of such problems is the chief work of the Physiology of Vision Committee of the Medical Research Council.

The Second Danish-Icelandic Expedition to Iceland, 1927.

By Dr. Niels Nielsen, Copenhagen.

OUR knowledge of the interior of Iceland is of quite recent date and still in part very incomplete, even to the point that there are districts which may be said to be utterly unknown to science. This applies both to topography and to geographical and geological conditions. The reason is that it is very difficult to push into the highlands of the interior, because different difficulties, each of which requires to be met by a special technique on the part of the traveller, combine to present obstacles to his passage as well as to his closer scientific investigation of the country.

In a purely practical way the coast districts have been known ever since the country was first inhabited, that is, for about a thousand years, and similarly certain tracks through the inner highlands, which one may suppose were considerably better known seven or eight hundred years ago than they were in the eighteenth and nineteenth centuries. Meanwhile, the last fifty years have made great changes in our knowledge of this region, inasmuch as a great advance has been made in the scientific investigation of the highlands, and at the same time in a practical knowledge of the country. This advance is due to a considerable number of able and energetic men of science and travellers, among whom one may name Winkler (1858), Preyer and Zirkel (1860), Keilhack (1883), Watts's various expeditions in the 'seventies, and Biziker (1900). Above all, one must mention the great work carried out by the distinguished Icelandic investigator, Thorvaldur Thoroddsen, who in the last two decades of the nineteenth century travelled over a very great extent both of the highlands and of the coast districts, and published numerous papers on the geography and geology of Iceland. We further owe to Thoroddsen a number of excellent handbooks which are among the most important aids in Icelandic exploration. Since 1898, when Thoroddsen's journeys ended, the work has been continued by

German, British, Icelandic, and Danish men of science, who have all contributed to our knowledge of the peculiar natural conditions of the interior of Iceland. During the War, Icelandic investigation came almost to a complete standstill, but since then a number of investigators have made journeys into the country, and the results are beginning to appear in various journals.

One link in the series of these resumed investigations of Iceland is contributed by the journeys accomplished in the years 1924 and 1927 under the name of the First and Second Danish-Icelandic Expeditions, under the leadership of the author of this article and the Icelander Palmi Hannesson. The costs of these expeditions were provided by the Danish-Icelandic Confederation Fund and the Danish Carlsberg Fund. With regard to the expedition of 1924, the reader may be referred to the articles already published,[1] but in what now follows a short synopsis will be given of the work accomplished in the expedition of 1927.

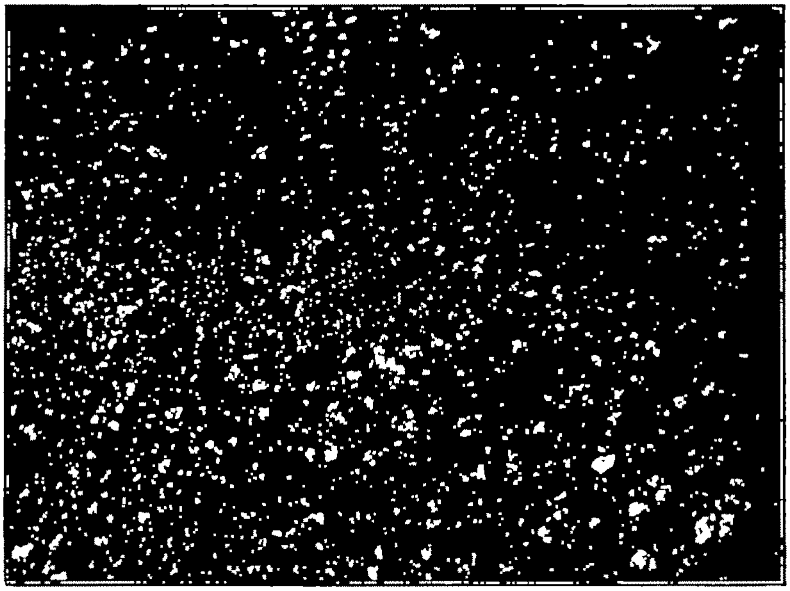

Fig. 1.—Surface of lava-gravel near Fiskivotn, Iceland. The storms, joined with the great porosity of the surface, make vegetation very scarce. In the foreground may be seen a little stunted Armeria.

The main lines of the plan were to push from the district near Hecla towards the western part of the great ice-field of Vatnajökull and to make investigations in the ice-free country west of the ice-field and its western part, the intention being to explore westward until contact was established with the districts south of Hofsjökull explored in 1924.[2] That has now been done, and the plan proved on the whole to be workable with the means and the man-power which were at our disposal.

The participators in the scientific work were Steinthor Sigurdsson, Palmi Hannesson, and Niels Nielsen. They were accompanied by a non-scientific colleague, an Icelandic schoolmaster Sigurdur Jonsson. The work lasted from the beginning of July until the middle of September, and from July 18 to Sept. 3 the expedition was cut off from all connexion with the inhabited district except that the Danish minister in Iceland, Fr. de Fontenay, was from July 30 to Aug. 5 the guest of the expedition and took part in the work.

By far the greatest part of the highlands of Iceland is extremely deficient in vegetation and may be described as desert; but this differs very much, as great parts are covered with ice the whole year through, especially the higher altitudes of the plateaux, which embrace most of the country and in many places extend right down to the coast. The parts of the highlands which are free from snow in summer are for the most part very sparingly overgrown, and it is only at long intervals that one comes upon oases. These conditions completely govern the technique of travel in Iceland, which is based on the use of Icelandic ponies, because it is only with their help that one is able to overcome the obstacles presented by ice-fields, lava-fields, barren stretches of sand and gravel, and, not least, the great number of rivers springing from the margins of the ice-fields.

On long journeys in country free from snow it is impossible to transport fodder for the horses,[3] because a horse can only carry fodder for himself to last about ten days, so that one must depend on the few and scattered oases already mentioned. The explorations of 1927 set out from two such oases near Fiskivötn and Illugaver, both known before. On these spots we established a base whence the work was carried on, partly on horseback, partly on foot, partly by the setting up of small intermediate stations in the desert tracts around.

The equipment consisted of tents, with watertight floors, sleeping-bags of lamb-skin, and vegetable provisions for nine weeks: on the other hand, the supply of meat was quite small, the intention being to furnish the expedition with animal food by hunting and fishing. We succeeded, thanks especially to our catches of trout, in getting what we needed. For transport of men and goods, seventeen horses were employed, of which, however, immediately after our arrival at Base No. 1, four had to be sent back to the inhabited district, because there was not grass to feed them all. So the number of our horses was properly thirteen. The scientific equipment consisted, *inter alia*, of a complete outfit for mapping and astronomical determination of position (wireless receivers for determining time and for meteorological intelligence), apparatus for meteorological observations, and a set of instruments for limnological work. We carried, besides, a good photographic equipment, both the usual plates and cinema-films.

[2] Niels Nielsen: "Plan til en Ekspedition til den vestlige Del af Vatnajökull og tilgrænsende Egne i Centralisland." *Geografisk Tidsskrift*, Copenhagen, 1927.

[3] Conditions are quite different when one has to do with ice-tracts and can employ sledges drawn by horses; cf. J. P. Koch's journey over the inland ice of Greenland with Icelandic horses, 1912–13.

Those who took part in the scientific work worked to some extent collectively and to some extent singly. Thus the cartographical work was mainly carried out by Sigurdsson, the limnological, as also the zoological and botanical investigations, were made by Hannesson, while I mainly occupied myself with geomorphological inquiries, especially concerning the morphology of vulcanism and tectonics. But collective work was much needed both for practical and for scientific reasons.

The results of the investigation can naturally not appear in their completed form until later, and then will probably be published as articles in journals in a widely used language, but a short survey of the materials collected can be given at once.

1. The results obtained give a series of new lights on topographical facts in the country west of Vatnajökull and the western part of that ice-mass; and on the basis of the triangulation carried out for the whole district and the detailed measurements carried out in certain cases, it will be possible to make a general survey map of the whole district and a map to smaller scale of different areas of especial geographical or geological interest. The working sketches already made show that the chief topographical lines, mountains, rivers, ice-margins, seashores, run essentially otherwise than has been hitherto supposed, and of a great part of the district it is certain that it was never before travelled in, far less mapped out.

2. The biological, and more especially the limnological, material will probably contribute to an understanding of the rigorous conditions under which animals and plants subsist in these regions, which may be described as the border-regions of the diffusion of life on the earth. A special investigation has been taken in hand of some peculiar lakes in the neighbourhood of ice-margins, which are marked by an extraordinarily rich fauna and flora, though its richness relates only to the number of individuals, not of species. Only two species of fish are found, namely, one of stickleback and one of trout, but by way of compensation the fish were very well-grown and fat; the trout weighed up to 4 kilograms. Another special research has been made into the peculiar plant-world which is found at times in the immediate vicinity of the ice-margin, and here forms such large and continuous oases that one can feed a small number of horses there for some days, a plant-world existing amid a number of concurring circumstances of a remarkable kind.

3. The geographical-geological material is very extensive and various in character. Of the topographical part, mention has already been made. In addition, there are numerous observations concerning volcanic action, which has been very violent and varied, in this part of the country. One finds, for example, typical fissure-eruptions with a great production of lava which has formed lava-fields covering many hundreds of kilometres. Again, we have single volcanoes with a mixed formation of the same type as Vesuvius, while the excrescences found at fissure-eruptions are so slight that they are difficult to find. In one of the volcanic zones the explosive activity has been very great and has led to the formation of a number of craters or 'Maarer' of many different types. The volcanic activity can be followed from the later period of the ice age down to the present day—the last outbreak which can be dated with certainty took place in 1913. Consequent on the volcanic phenomena, many fumaroles and hot springs are found.

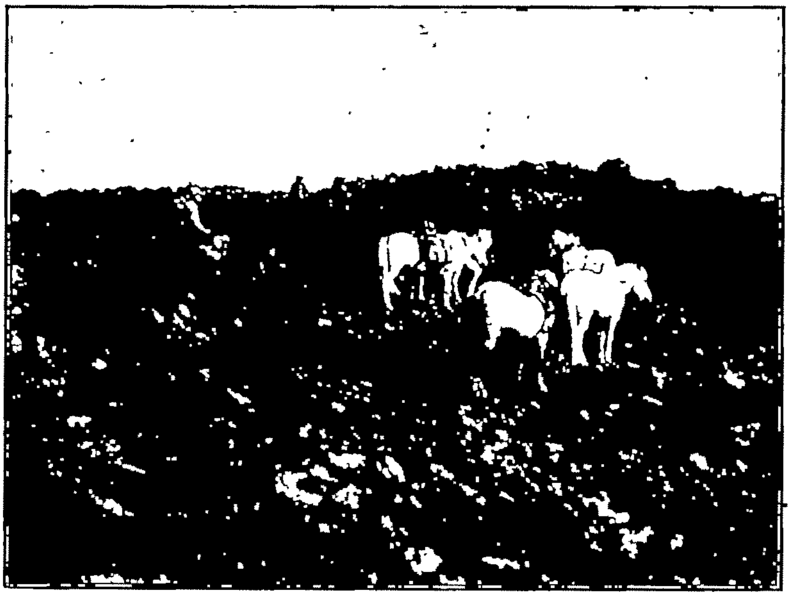

FIG. 2.—In the lava-fields immediately west of Vatnajokull. The horses are standing on an old lava-stream of somewhat loose sand, while the two men behind are walking on quite recent lava which is very difficult to cross. The demarcation of the two streams is seen quite clearly.

The country west of Vatnajökull is further remarkable for being a very disturbed country in a tectonic sense. A great part of the region is broken up by earthquakes. The displacements have especially taken place along lines running in the direction S.W.—N.E. and have divided the country into a number of ridges with intervening depressions. Some of these displacements go back to the ice age, while others are quite recent, in any case not more than some few thousand years old.

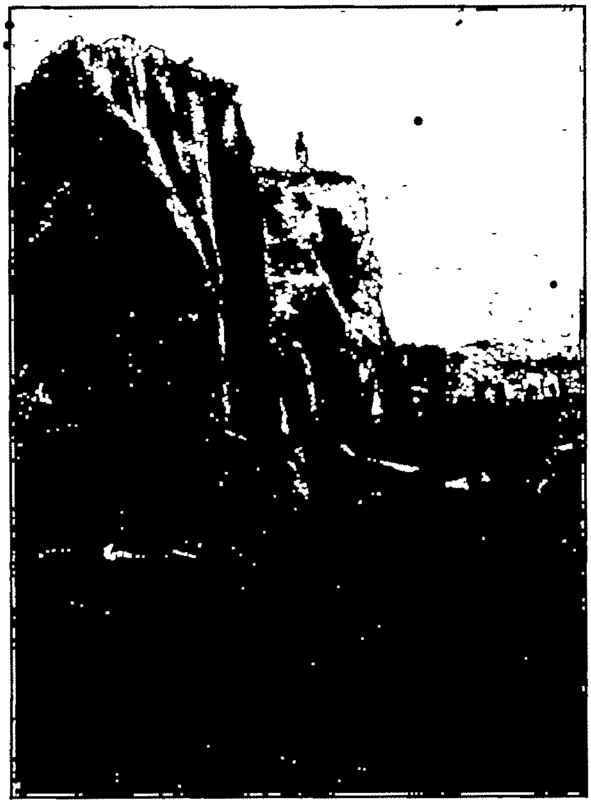

FIG. 3.—An earthquake-rift in the lava-fields west of Vatnajökull.

As a third factor in landscape-formation one may mention the ice, which has many times spread from the neighbouring Vatnajökull over the whole country, and the effect of which, both in earlier times and in modern times, has been the subject of study.

In this landscape, the origin of which, as has been stated, must be referred to three different sets of factors, a whole series of transforming forces are at work at this moment, and some of these have been specially investigated, because the conditions here in certain respects are abnormal. A very special rôle, for example, is played by the wind, the erosive power of which is very violent and is the cause of production of frightful sandstorms, which in their strength remind one of those that take place in the great desert regions of Asia and Africa. Another very real factor in erosion is the snow, which, together with the masses of water set free by its melting, greatly contributes to the transformation of the landscape. The reason why the above-mentioned factors play so great a part in this work, and can be studied with comparative ease, is that nearly the whole district is deficient in surface streams. Apart from the great rivers of melted ice, one finds only a few short streams, since the whole surface consists of very porous kinds of rock which absorb water with avidity and carry it underground a great distance until it emerges as springs of surprising abundance.

The expedition has met with great kindness and support on many sides both in Iceland and in Denmark, the conditions of work have on the whole been good, and the work has been carried out without serious misfortune to man or beast.

Obituary.

PROF. P. H. VON GROTH, FOR. MEM. R.S.

GEHEIMRAT PAUL HEINRICH RITTER VON GROTH, who died on Dec. 2, 1927, was born on June 23, 1843, at Magdeburg. His father was a portrait painter. His early academic studies were pursued first at the Bergakademie at Freiberg (1862–65) and then at the University of Berlin (1865–67), where he obtained his Ph.D. degree in 1868. He was successively assistant in the Department of Physics in the University (1868–70), reader of mineralogy and geology at the Bergakademie in Berlin (1870–72), and in 1872 was appointed professor in the newly constituted University of Strasbourg, where he remained for eleven years until his promotion to the chair at Munich. It was during Groth's tenure of office at Munich that the most important work of his life was accomplished. In 1874 he published his "Tabellarische Übersicht der einfachen Mineralien"—a comprehensive list of the mineral kingdom, containing not only a systematic classification of species, but also a critical survey of views on their chemical composition; subsequent editions with much new material appeared in 1882, 1889, 1898, and were followed in 1921 by a new survey, "Mineralogische Tabellen," in conjunction with Mieleitner. In 1876 he published his famous "Physikalische Krystallographie," a most readable and suggestive treatise which was for many generations of teachers and students an attractive introduction to a science that had previously been presented in a very unattractive form. Sir Lazarus Fletcher has recorded the fact that he was led to take up the study of the subject by happening to see a copy of the book in that year. Subsequent enlarged and revised editions appeared in 1885, 1895, 1905.

In 1877, Groth started the first volume of the *Zeitschrift für Krystallographie und Mineralogie*, which became universally known as Groth's *Zeitschrift*. This he edited with great skill for thirty-nine years, enlisting the co-operation of a large number of mineralogists from all countries; it was conspicuous for its international character and for the value not only of the original papers, but also of the abstracts which it contained. In a memoir which appeared shortly before his death in the *Zeitschrift*, he gave an account of its inception and a history of its progress during the period of his editorship. The fiftieth volume (1923) was a

Supplement to NATURE

No. 3038 JANUARY 21, 1928

On the Rotation of the Earth and Astronomical Time.

By W. de Sitter, University of Leyden.

Absolute Time and Practical Measures of Time.

NEWTON'S "Principia" begins with the definitions of some technical terms, such as 'mass,' 'force,' etc. Newton then continues as follows:

> "Nam Tempus, Spatium, Locum et Motum, ut omnibus notissima, non definio. Notandum tamen, quod vulgus quantitates hasce non aliter quam ex relatione ad sensibilia concipiat. Et inde oriuntur praejudicia quaedam, quibus tollendis convenit easdem in absolutas et relativas, veras et apparentes, mathematicas et vulgares distingui.
>
> "I. Tempus Absolutum, verum, et mathematicum, in se et natura sua absque relatione ad externum quodvis, aequabiliter fluit, alioque nomine dicitur Duratio: Relativum, apparens, et vulgare est sensibilis et externa quaevis Durationis per motum mensura (seu accurata seu inaequabilis) qua vulgus vice veri temporis utitur, ut Hora, Dies, Mensis, Annus."

The few words which Newton puts in parentheses contain the great problem: How are we to decide whether a given measure of time is accurate or not? We measure time by different 'motions,' of the sand in an hour-glass, of the hands of a clock (hours), of the earth on its axis (day), of the moon round the earth (month), the earth round the sun (year), or others. If these different methods do not give the same result, *and they do not*, how are we to know which is to be preferred, which is the best approximation to the true, absolute, mathematical time?

It is one of the fundamental characteristics of natural science that we never get beyond an *approximation*, and this for two reasons. The first of these is that the motions that we use for measuring time must be observed, and all observations are affected by errors, and can never be absolutely accurate. The other is that Nature never offers us simple and undivided phenomena, or 'motions,' to observe, but always infinitely complex compounds of many different phenomena. Each simple phenomenon can be described mathematically in terms of the accepted fundamental laws of Nature; to interpret the complex phenomena of daily experience we must analyse them into their simple components, isolate these, and from each separately draw our conclusions. We can never be sure that we have carried this analysis to its full exhaustion and have isolated one single simple phenomenon, to which we can apply our mathematics. We might, indeed, take a different point of view and argue that the phenomena of Nature are simple, and that it is we who introduce the complication, forced to do so by the limitations of our power of mind and our mathematics, which do not allow us to grasp the sublime simplicity of Nature otherwise than by the devious route of first splitting it up into partial aspects, so chosen that we can master them by our mathematics, and then recombining these to an approximate representation of the whole. However this may be, we cannot but use the only means at out disposal, and if the truth be one and simple, we can only comprehend it as a synthesis of many constituent truths.

The simple constituent motions into which we decompose the actual phenomena are described in terms of the laws of mechanics and the time. This time, which is thus the 'independent variable' of our differential equations, or laws of Nature, is Newton's mathematical (or true, or absolute) time. Once the observable quantities have been expressed mathematically in terms of the time, it is very easy inversely to derive the time from the observed values of these quantities.

In our choice between different motions used to measure time, or, as we may say, between different 'clocks,' we are thus guided by two considerations: which can be most accurately observed, and which 'runs' most accurately, that is, which represents the best approximation to an isolated simple phenomenon of which we know the laws.

ASTRONOMICAL TIME.

The standard clock, to which all other measures of time are referred for comparison, is the rotating earth. In fact, we know of no other motion which is so purely representative of an isolated simple phenomenon, so free from 'perturbations.' The time measured by the rotation of the earth has for immemorial ages been used by astronomers as their standard of reference. It is called *astronomical time*.

The motions of the other heavenly bodies can, of course, also be used as a measure of time. Their mathematical expression in terms of the time is less simple, and the determination of the time from the observed motions thus demands a greater amount of computation. Also they cannot be observed with the same accuracy, the motions being slower and the bodies far away. But within the limits of uncertainty, they all ought to give the same time; that is, the ratio of the day and the month, and of the day and the year, ought to be constant through all ages, after due allowance has been made for known perturbations.

TIME MEASURED BY THE MOON: THE SECULAR ACCELERATION.

These ratios, however, are *not* constant. The great astronomer Halley discovered that the month, measured in astronomical time, is continually getting shorter. Whether, measured in the true or mathematical time, the month gets shorter or the day longer, or both change, we have no means of saying: we only know that the number of days in a month is becoming smaller. The change is very minute: if it continues at the same rate, it will take 250 million years for this number to diminish by one unit. The length of the month at the present time diminishes by $\frac{1}{17}$ of a second per century; in other words, the motion of the moon referred to astronomical time is accelerated.

When two clocks do not show the same time, the difference may be constant, or it may be variable. If it increases or diminishes regularly, the two clocks have different *rates*; one of the clocks, say A, loses time as compared with the other, say M; or one hour of A is longer than one hour of M. If also the difference of the rates is not constant, but changes regularly with the time, then one of the clocks is *accelerated* with regard to the other, and the other is retarded with reference to the first. If we call T the time as read from clock A and t that given by clock M, the three cases considered are represented by the following mathematical formulæ:

$$(1)\ t - T = a,$$
$$(2)\ t - T = a + bT,$$
$$(3)\ t - T = a + bT + cT^2.$$

The formula (3) represents the case of the earth and moon, used as our clocks A and M. The time as derived from the moon's observed longitude is not uniform as compared with astronomical time, but contains a term $20^s \times T^2$, if T is expressed in units of a century. This is technically known as the *secular acceleration* of the moon's motion. It was discovered by Halley, who found that he needed it in order to represent by one formula the modern observations as well as eclipses observed by the ancient Babylonians and by the Arabian astronomer Albategnius (ninth century A.D.).

The presence of this term proves that our simple theory of the motion of the moon, taking account of no other forces than the general attraction by Newton's law, is incomplete. Consequently, either some minute gravitational effect has been overlooked in elaborating this theory, or some other cause must be acting in addition to it. Newton[1] suggested that this other cause might be a slow increase of the mass of the earth by the addition to it of the "vapours escaping from the atmospheres of the sun and the stars and the tails of comets, which by their gravity fall down into the atmosphere of the earth and the other planets and may there be condensed and converted into water and watery vapours, and subsequently by slow heating be changed by and by into salts and sulphurs, and tinctures and mire, and mud and clay, and sand and stones, and corals and other terrestrial substances."

We now know that this cause—which in modern language we would call the fall of meteorites—is real, but incapable of explaining even a very small fraction of the observed acceleration. Tobias Mayer, in the middle of the eighteenth century, was the first to suggest that the change might not be primarily in the month, but in the day, the rotation of the earth being retarded by the friction of the tides. This suggestion, however, does not appear to have attracted any attention at the time. Laplace, in 1787, found a perturbation by the gravitational influence of the planets on the motion of the moon, which had been hitherto overlooked. According to his computations, this would be just sufficient to explain the observed acceleration of the moon's motion, the day not being affected. If this were so, there would be no discrepancy; the two clocks would be in perfect agreement. Adams, however, in 1853, carried Laplace's computations to a further order of approximation and found that this cause explains little more than one-half of the observed acceleration, giving in fact a term $11^s \times T^2$. There thus remained unexplained about $9^s \times T^2$.

---

[1] "Principia," Book III., just before the *Scholium Generale*.

FLUCTUATIONS OF THE MOON'S LONGITUDE.

This, however, is not the only unexplained discrepancy in the moon's motion. In addition to it, the moon shows irregular deviations from its path as prescribed by theory. It is sometimes in advance of its theoretical position and sometimes it is left behind. The difference can run up to 15 or 16 seconds of arc. In other words, since the moon takes about two seconds of time over one second of arc, the time shown by the 'clock M' may occasionally be about half a minute slow or fast on astronomical time. These irregularities, called *fluctuations*, were discovered by Newcomb. He suspected them already in 1875, but it was only in 1903 that he published an entirely convincing proof of their reality. Before about 1630 the observations are too inaccurate to enable any conclusions to be drawn. At that time the moon was about 30 seconds slow on astronomical time. About 1670 it began to gain, so that in 1720 it had made up its arrears. It then continued to gain, and was nearly 30 seconds in advance by 1785. Then it started to lose again, being caught up by the theoretical moon in 1865, and left behind more and more until about 1900, when it started to gain again. It has, however, only succeeded in diminishing its arrears from about 30 seconds in 1900 to about 18 in 1918, and has lost again in the last few years, being some 23 seconds slow at the present time.

It should be understood that these fluctuations are additional to the secular acceleration, and they are of a very different nature. The secular acceleration is a steady increase of the rate of the lunar 'clock.' If it is graphically represented by plotting on co-ordinate paper the deviations of the moon's observed position from the theoretical one, the resulting curve is a parabola. If the change of the rate is not uniform, then the curve will differ from a simple parabola, but it will always be a smooth curve with a continuous curvature and without any sharp bends. The fluctuations, on the other hand, show a very different character. When plotted on co-ordinate paper, they have the appearance of a series of straight lines with sharp bends where two lines meet. Thus from the appearance of the observed deviations we would be inclined *a priori* to ascribe them to two different causes.

It has already been remarked that the observations prove only that there is a difference between the time as shown by the two 'clocks' A and M, but do not enable us to decide which of the two is correct. There is, however, one crucial test, which is very obvious, though not so very easily applied. If the clock A is in error, that is, if the astronomical time differs from the mathematical time, then not only the moon, but all the other heavenly bodies as well, must show deviations from their theoretical motions. Now the moon is not only our nearest neighbour, in consequence of which the observations of its position are more accurate than those of other bodies, but it also moves much more quickly than most others, so that the irregularities run up to a larger amount in the same time. The consequence of this is that irregularities in the moon's motion have been discovered earlier than in the motions of other bodies.

THE SUN AND THE PLANETS.

It was only in 1906, about two centuries after Halley's discovery of the secular acceleration of the moon, that Cowell detected a secular acceleration in the longitude of the sun. His result has been confirmed by later researches, and it has also been found that the planet Mercury, which can be very accurately observed on the occasions of its transits across the sun's disc, shows a similar acceleration. The most recent discussions lead to a secular acceleration of the longitudes of the sun and Mercury corresponding to a term $40^s \times T^2$, *i.e.* about 4·4 times as much as the unexplained acceleration of the moon. If this is ascribed to a retardation of astronomical time, *i.e.* of the rotation of the earth, then the corresponding lengthening of the day is $\frac{1}{400}$th of a second per century. On the other hand, several astronomers have found fluctuations similar to those of the moon in the longitudes of the sun, Mercury, and Venus. Brown was the first who produced strong evidence of this (in 1914), and lately many investigations have established the similarity of these fluctuations with those of the moon beyond any reasonable doubt. Whenever the moon is losing on astronomical time, the sun and planets are also losing, and when the moon is gaining, the sun and planets are also gaining. Thus, for example, from 1876 to 1897 the moon lost about 15 seconds, and from 1897 to 1918 it gained about 11 seconds. The sun and planets have in these intervals lost 19 seconds and gained 14 seconds respectively, and similarly for other intervals, the moon's loss or gain being always about four-fifths of those of the sun and planets.

All this points to the astronomical time, that is, to the rotating earth, as the chief offender, in complicity, however, with the moon. We are thus confronted with the question how a change in the rate of rotation of the earth, that is, in the length of the day, can be explained, and with the further question whether the cause which produces this change can also affect the motion of the moon. The problem certainly looks forbidding enough.

If we return to our representation by 'clocks,' we have now *three* clocks: *A*, the rotating earth, giving astronomical time; *M*, the moon; and *S*, the sun and planets. The sun and the planets Mercury and Venus are treated as *one* clock, *S*, since they agree amongst each other within the limits of accuracy of the observations, but they do not agree with *M*. The observations of the other planets are not sufficiently accurate to be used for comparison. There is, in fact, a fourth clock, *J*, namely, the satellites of Jupiter, of which accurate observations exist. This, however, does not agree with either *M* or *S*.

The problems which are raised by this further disagreement are so complicated that I will leave them out of consideration in this article. We will restrict ourselves to the three clocks *A*, *M*, and *S*. We find that both *M* and *S* are uniformly accelerated with regard to *A*, and the acceleration of *M* is between a quarter and a fifth (0·23) of that of *S*. Further, both are losing or gaining simultaneously, at irregular intervals, the loss or gain of *M* being four-fifths of that of *S*. We can, however, choose any other clock as our standard of reference instead of *A*. If we choose *S*—and I may say here at once that our final conclusion will be that *S* keeps true mathematical time—then our observational data are that both *A* and *M* are uniformly retarded, the retardation of *M* being between three-quarters and four-fifths (0·77) of that of *A*, and further, both *A* and *M* are alternately gaining and losing simultaneously, the gain or loss of *M* being one-fifth of that of *A*. It should be kept in mind that this division of the observed phenomena in two classes, the uniform retardation and the alternate gain and loss, is introduced by us in order to prepare them for mathematical treatment. In Nature there is only *one* phenomenon, the sum of the two, and our mode of cutting it up may be very unnatural.

It is, however, necessary to cut up our problem into simpler ones, because our mathematics would not otherwise be able to deal with it. Mathematics, after all, is only a device to relieve us from thinking, as one of my astronomical friends likes to say. We may compare it to the motor-car, which is a device to relieve us from walking. We will make a free use of this convenient vehicle, but we will thereby unavoidably lose a little of the intimacy with the landscape which the pedestrian enjoys.

TWO POSSIBLE EXPLANATIONS.

Amongst all the causes that have been imagined for a change in the rate of rotation of the earth, there are only two which can stand the test of critical scrutiny. These are: first, changes in the size or shape of the earth, or the distribution of mass inside the earth, leading to a change of the moment of inertia with reference to the axis of rotation; and second, tidal friction.

The first cause can act both ways: when the moment of inertia is increased, the rotation becomes slower; when it is diminished, quicker. The motion of the moon is not affected. If the changes of the moment of inertia take place discontinuously, the rate during the intervals between the changes is constant: the graphical representation of the longitudes of the heavenly bodies will be just such a series of straight lines as we found characteristic of the *fluctuations*. The only difficulty is that the moon should show exactly the same fluctuations as the sun and the planets, and not four-fifths of them, as it does. In other words, this cause affects our 'clock *A*' only; it should leave *M* just as true to mathematical time as *S*.

The second cause can only retard, and never accelerate. If the tidal friction remains constant throughout the ages, the retardation must be uniform, and we shall get a representation by a parabola, as observed in the secular acceleration; if it is not uniform, but changes from time to time, we shall get a series of parabolas, but they will still form a smooth curve, without sharp bends. A characteristic difference of this cause from the first is that it does influence the moon's motion. The tidal wave is caused by the attraction of the moon, and inversely it must attract the moon, thus creating a tendency to accelerate its motion. This causes the moon, by centrifugal force, to recede from the earth, and thereby, in accordance with Kepler's third law, its period of revolution is increased, *i.e.* the 'clock *M*' is retarded. When the moon is nearest the earth, at its perigee, the tides are higher and the ensuing force is greater than the average; consequently, the distance increases more than the average, and by the time it has arrived at the opposite end of its orbit, the apogee, it has swung farther out. Here the force is less than the average, the outward tendency is less, and the moon recedes less than the average. The consequence is that the difference between the greatest and least distances is enhanced: the eccentricity is increased.[1] To convert this qualitative reasoning into a quantitative one, that is, to calculate the exact amount of increase of the mean distance and the eccentricity, it would be necessary to have a detailed knowledge of the forces acting.

The forces acting in the tidal friction are extremely complicated. It has been proved that neither the tides in the body of the earth, nor those in the great oceans, can produce enough friction to explain even a very small part of the observed retardation. The effective friction occurs in the shallow seas and narrow straits, such as the English Channel, the Straits of Malacca, the Bering Sea, and others. The tidal current runs up these straits or shallow seas from the ocean, and spends part of its energy in friction against the coasts and the bottom. The energy thus dissipated (which is, of course, converted into other forms of energy, for example, by a small rise of temperature of the water) is taken from the rotation of the earth, which is thus always retarded, whether the current happens to run against the rotation, or with it as in the case of the English Channel. The reaction on the moon takes place by the intermediary of the mutual attraction of the moon and the small secondary waves set up from the areas of dissipation as centres. Jeffreys has calculated the amount of energy thus taken from the rotation per second, and finds that those shallow seas in which the currents are known with sufficient accuracy to make the computation possible, explain about one-third of the observed retardation. If we reflect that more than two-thirds of this is contributed by the Bering Sea alone, and that there are many more shallow seas not included in his investigation, especially in the polar regions (for example, to the north of Asia), where presumably the friction is increased by the presence of ice, it does become very probable that this is the true explanation of the retardation of the rotation of the earth and of astronomical time. We may also remark that it is scarcely to be expected that the friction will be exactly the same throughout all time. It is thus natural to suppose the retardation to be variable. The observed secular acceleration is, from this point of view, the average over the last 20 or 25 centuries, but there may have been oscillations.

Can the variability of the secular acceleration be invoked to explain the fluctuations? To begin with, as has already been pointed out, it will never give rise to sharp bends such as occur in the observed fluctuations. But there is a much more cogent reason why it can only explain a relatively small part of the fluctuations. Friction can, of course, never *accelerate* the rotation; it must always retard it. Now the fluctuations consist of alternate retardations and accelerations, and sometimes the accelerations are larger than the retardation of tidal friction, so that the total effect is an acceleration. This circumstance sets a limit to the fraction of the fluctuations which can be due to the variability of tidal friction. Certainly not more than one-half of the observed fluctuations could be explained in this way.

EFFECT OF TIDAL FRICTION.

So far we have considered the effect on the rotation of the earth. We have also seen that the mean distance of the moon must be increased, and consequently its mean motion diminished, and that its eccentricity will probably also be increased. To calculate the retardation of the moon and the increase of its eccentricity corresponding to a given retardation of the earth, we would have to follow step by step the play of the forces in the small secondary tidal waves produced by the friction in the shallow seas. Here the ground becomes too difficult even for the mathematical motor-car. We must take a flying machine to cross over this jungle and land us safely at the other side. Such devices, which can lift us from the solid ground of actual computation to bring us by a short cut to some remote point without taking any notice of the intervening country, are provided by the 'general principles' of theoretical mechanics. The machine that we use in this case is called the 'principle of conservation of angular momentum.' If the earth's rotation is slowed down, the angular momentum of the system earth–moon is diminished, and the moon must make up for that by increasing its own angular momentum, which it can do by increasing its mean distance, by increasing its velocity of revolution (mean motion) or by diminishing its eccentricity. The increase of the mean distance is the most effective of these means, and it is the one that the moon will choose. It entails a decrease of the mean motion, and the exact balance between these two effects is determined by Kepler's third law. We have seen that probably the eccentricity will also be increased, and consequently the mean distance has to be increased more than if the eccentricity remained constant. How much more, the general principle cannot tell us.

---

[1] This explanation of the increase of the eccentricity is borrowed from Darwin, to whom it was suggested by Lord Kelvin. It is, as Darwin remarks, not a rigorous reasoning, but still it is sufficient to make an increase of the eccentricity appear more probable than a decrease.

If the eccentricity did not change, the increase of the mean distance would be such as to make the retardation of the moon's motion two-thirds (0·67) of that of the rotation of the earth. We know by observation the retardation of the rotation and we can thus easily calculate the increase of mean distance for constant eccentricity. On the other hand, we also know the actual retardation of the moon's motion, and therefore, by Kepler's third law, the actual increase of its mean distance. The excess of this over the computed value must be what is needed to compensate the increase of the eccentricity. In this way we find that to the observed ratio of 0·77 of the retardation of the moon and that of the earth, corresponds an increase of the eccentricity of the moon's orbit by one fifty-millionth, or one three-millionth of itself, per century. This, of course, is an extremely minute quantity. It can never be detected by direct observations, and can, so far as I can see, have no influence on any other observable phenomenon, but it is sufficient to increase the ratio just mentioned from 0·67 to 0·77.

CHANGES OF THE EARTH'S MOMENT OF INERTIA.

We return to the consideration of the first cause. How can the moment of inertia of the earth be changed? The change must be due to some displacement of mass on the surface or in the inside of the earth. But the displacements needed to explain the observed changes of rate are enormous. In 1918 the length of the day changed suddenly, or at least within a very short interval of time, from $\frac{1}{580}$th of a second longer to $\frac{1}{580}$th shorter than the average, a shortening of one twenty-five millionth of its length. If the whole of the Central Asian Highlands, from the Himalaya to the Kuen-lun mountains (both included), had at that time been sunk into the earth, their mean height being reduced to sea-level, the resulting shortening of the day would have been only one hundred millionth of its length, or one-fourth of what is required. This example shows that it is hopeless to look for local displacements of mass as an explanation of the observed changes. If, however, the displacements are world-wide, they need not be so large. A uniform shrinkage of the whole earth, decreasing its radius by about 5 inches, would be sufficient to produce the shortening of the day which happened in 1918. Even this would be rather a crude way of producing the required effect. It can be attained by a very slight adjustment of the shape of the layers of equal density in the inside of the earth, of which the effect on the dimensions of the outer surface need not exceed a fraction of a millimetre. But in any case the origin of the change must be in the deeper layers, and it must be of a world-wide, and not of a local, character.

This, then, must be the explanation of the sudden changes of rate of our 'clock *A*,' which are revealed by the fluctuations in the observed motion of the moon, the sun, and the planets. There is, in this case, no change of angular momentum: the rate of rotation adjusts itself instantly to the altered size or shape of the earth, so that the angular momentum of the earth by itself remains constant, and no call is made on the moon for any compensation. The true length of the month is not affected; the 'clock *M*' is not concerned at all.

COMBINATION OF THE EFFECT OF THE TWO CAUSES.

We found, however, that the clock *M does* show real fluctuations to the extent of one-fifth of those of the clock *A*. Now it must be remembered, as has already been remarked above, that the splitting up of the total deviation from uniformity into a uniform retardation—of which about four-fifths is transferred to the moon—and fluctuations—in which the moon takes no part—that this division into two parts is entirely artificial. If the retardation is not uniform, it can explain a part of the fluctuations (not more than one-half, as we have seen), and of this part four-fifths will be transferred to the moon. Our conclusion is thus that three-quarters of the fluctuations in astronomical time are produced by changes of the size and shape of the earth, and one-quarter by variability of the coefficient of tidal friction. Four-fifths of this quarter, or one-fifth of the whole, is then transferred to the moon.

Thus all observed phenomena are satisfactorily explained by the simultaneous action of two causes. It should be remarked that the two causes are entirely independent of each other, acting at different times. But we can only observe the sum of their separate effects.

The word 'satisfactorily' perhaps requires some qualification. When do we call an explanation satisfactory? If we are satisfied when it shows how the observed phenomena follow naturally from causes which we know are acting, or at least are possible, then the explanation here offered is satisfactory. But if we require that the explanation will enable us to *predict* the phenomena for the future, or even for the present or the past, *i.e.* to assert that they must of necessity occur or have occurred, and to calculate their amount from known data, then the explanation is very unsatisfactory indeed, for if it is true, then the phenomena are essentially *unpredictable*. We have no means of saying when a new change of the size or shape of the earth may happen, or in what direction or how large its effect will be, nor can we predict when the coefficient of tidal friction will change, or by how much.

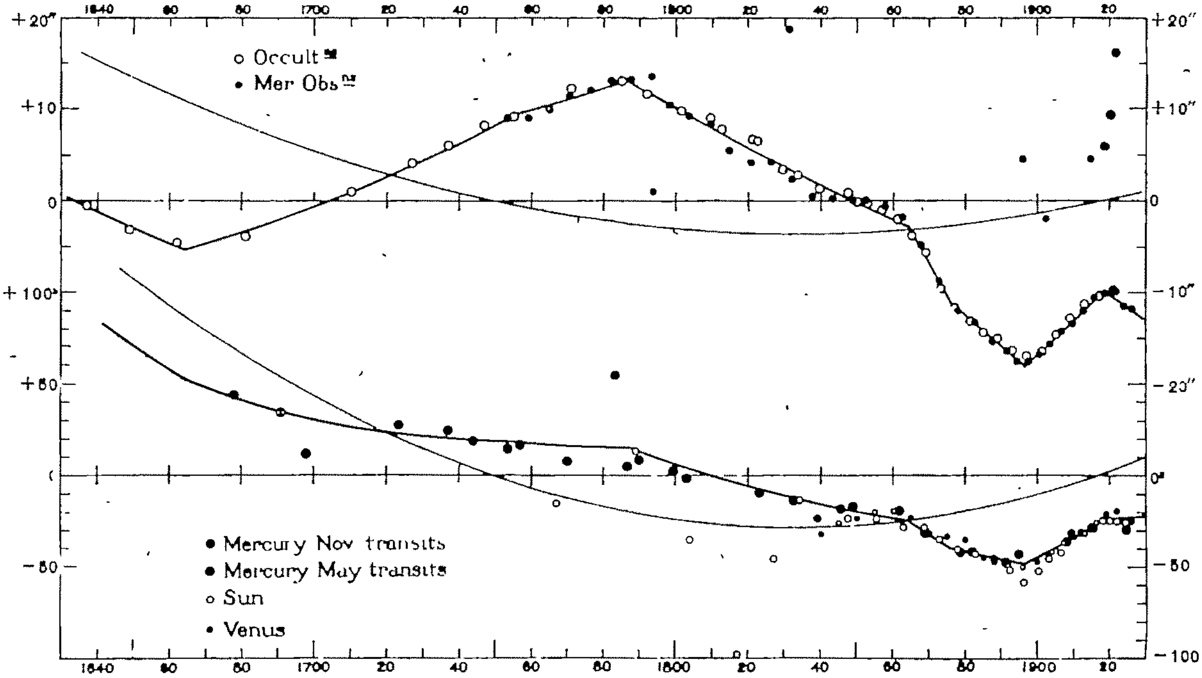

FIG. 1.—SECULAR ACCELERATIONS AND FLUCTUATIONS IN THE LONGITUDES OF THE MOON, THE SUN, VENUS, AND MERCURY.

The curves represent the combined action of two causes (A) and (B). The cause (A) consists in changes of the size or shape of the earth or the distribution of mass inside the earth. It produces discontinuous changes in the length of the day. The adopted excesses $\Delta\tau$ of the length of the day over its average value are:

(A)

Before 1664	$\Delta\tau = 0^{s}\cdot00000$
from 1664 to 1755	$+0\cdot00134$
„ 1755 „ 1786	$+0\cdot00089$
„ 1786 „ 1864	$-0\cdot00091$
„ 1864 „ 1876	$-0\cdot00357$
„ 1876 „ 1897	$-0\cdot00186$
„ 1897 „ 1918	$+0\cdot00153$
after 1918	$-0\cdot00186$

The cause (B) is the retardation by tidal friction. It produces a continuous lengthening of the day, of which the adopted amounts are:

(B)

Before 1745	$d\tau/dt = +0^{s}\cdot0024$ per century
from 1745 to 1870	$+0\cdot0013$ „
after 1870	$+0\cdot0037$ „

The average over the last 25 centuries is an increase of $+0^{s}\cdot0022$ per century.

The upper curve is (A) + 0·23 (B), and the lower one is (A) + (B). Against the upper curve are plotted the observed deviations of the moon's longitude from its purely gravitational value, computed with astronomical time as independent variable. Against the lower curve are similarly plotted the observed deviations of the sun, Venus, and the transits of Mercury. A scale of seconds of arc is added to the upper curve, and a scale of seconds of time to the lower one. This latter thus gives the correction that must be applied to astronomical time in order to reduce it to uniform (or 'absolute') time.

The lower curve has been drawn on a smaller scale than the upper one, corresponding to the smaller accuracy of the observations of the sun and planets compared with those of the moon. In forming a judgment of the deviations, it should be borne in mind that the older observations are far less accurate than the modern ones; especially, the observations of the sun previous to about 1835 (the date of Airy's accession to Greenwich) are very untrustworthy. Of the modern observations, only those of the sun of 1896·5 and 1900·5 deviate more than would be expected by the accidental errors of observation. Of the transits of Mercury, that of November 1782, which was almost a grazing transit, and very difficult to observe, is the only one showing a serious deviation from the curve.

The thin lines are the secular accelerations. The null-line has been so adjusted as to make these zero for 1750·0 and 1917·1.

The accompanying diagram (Fig. 1) gives a representation of the observed facts compared with the explanation. For the interval of nearly three centuries from 1637 to 1927, seven changes in the rate of rotation and two in the rate of retardation have been assumed. These are sufficient to represent the observations, with only very few exceptions, within their limits of uncertainty. Of course, there have probably been many more smaller changes, the effects of which are indistinguishable from the unavoidable errors of the observations.[3]

MECHANICAL CLOCKS.

One further point I should like just to touch upon. We have throughout spoken of the 'clocks' *A*, *M*, and *S*, representing the rotating earth, the moon, and the sun and planets respectively. But what about clocks in the accepted sense of the word? Can a mechanical clock be expected to keep mathematical time, that is, can it be considered as a sufficiently approximate realisation of one simple natural phenomenon, obeying one definite law without sensible perturbations? Before the application of the pendulum to clocks by Huygens, no timekeeper could be relied upon for more than a few hours. Even in the end of the eighteenth century, mechanical clocks were still so much distrusted that the regular astronomical practice was to make a 'determination of time,' that is, to take a reading of the standard clock *A*, before and after every observation of which it was essential that the time should be known accurately. The manufacture of precise clocks made great strides in the nineteenth century, but still, not many years ago, astronomers used to get rather uneasy when, as a consequence of bad weather, they had to rely on their clocks for any length of time, say a week or a fortnight. The invention of the free pendulum clocks has suddenly altered the aspect of the problem. One of these clocks has been left entirely to itself, being, however, kept under rigorous control, at the Observatory at Greenwich during the greater part of a year, and its rate has been absolutely invariable (apart from a very slight retardation due to a slow lengthening of its pendulum by sagging to the extent of, if I remember rightly, something like a fifth of a micron per month). It looks as if this clock could be depended on to keep time within a few hundredths of a second for a period measured in years instead of weeks.

Can, then, these wonderful clocks, if this expectation should turn out to be confirmed, be of use as a control on the uniformity of astronomical time, like the clocks *M* and *S*? Can the handiwork of man compete with the heavenly bodies? That depends on *which* time it will keep; and this, unfortunately, we are unable to tell. If the attraction of the earth remains constant, the clock will keep mathematical time. The change of gravity by the change of centrifugal force in consequence of the change of the rate of rotation of the earth is too small to be taken into consideration. It is, however, scarcely to be expected that the readjustments of masses in the bowels of the earth, which alter the earth's moment of inertia, will have no effect on its attraction. But how this effect will be we cannot say; it might happen to be negligible; it might by some improbable accidental coincidence be such as to make the clock keep astronomical time instead of mathematical time: it cannot be predicted.

It seems probable that such a change of rate as occurred in the rotation of the earth in 1897 and in 1918 would be shown unmistakably by the free pendulum clock. We must expect, then, that these clocks will show discontinuities in their rates at the same epochs as the earth. They will probably *not* be the *same* discontinuities, but of the same order of magnitude, and the comparison of the pendulum with the earth may perhaps help us a little towards the understanding of the causes which produce these changes.

---

[3] This article was in print before the recent transit of Mercury of Nov. 10, 1927. The observed times of this transit, so far as they have been published, appear to confirm the 'prediction' by the formulæ on which Fig. 1 is based. It has generally been observed from 20 to 40 seconds too early, the formula giving 29·8. Evidently no considerable sudden change of the moment of inertia has yet occurred since the one in 1918.—W. de S.

Printed in Great Britain by R. & R. Clark, Limited, Edinburgh.

Festband in honour of his eightieth birthday and contained papers by many of his old pupils, representing twelve countries.

In 1878, Groth's "Catalogue of the Strasbourg Collection" not only showed how active he had been in getting together an important teaching collection in six years, but also served as a model for future mineral catalogues. His reputation as the foremost teacher of mineralogy and crystallography had been firmly established when, in 1883, he was transferred to Munich as professor of mineralogy and Director of the State Collection. His department at Strasbourg had been remarkable for its international character; young men from all the countries of the world, who were destined to be the professors of the next generation, flocked to his laboratory; and at Munich the new department preserved the same character. Here again he built up a great collection and inspired a remarkable succession of researchers; a guide to the collection appeared in 1891, an introduction to the study of precious stones in 1887, an introduction to chemical crystallography in 1904, the elements of physical and chemical crystallography in 1921. But his energies were mainly concentrated on a sequel to his life's work in the form of a vast book of reference—a complete dictionary of the physical and chemical characters of crystallisable substances—mainly based upon the material contained in fifty-five volumes of the *Zeitschrift*. "Chemische Krystallographie" appeared in five volumes between 1906 and 1919, and is an invaluable work of reference.

A life so strenuously devoted to teaching, to the writing of treatises and text-books, to the organisation of university departments, to the inspiration of students, and to the supervision of their investigations, left little time for research. Except through the work of his pupils, the name of Groth is not associated with any great discovery. But he was always occupied in welcoming and in fostering new ideas, and he always had problems for his students to work out. At the beginning of his career he made a striking study of changes of form in the crystal produced by the substitution of one element or radicle for another, especially among organic compounds, and introduced the term 'morphotropy' for this effect; it guided his masterly studies on the composition of minerals; and the connexion between chemical composition and crystalline form was always his chief interest. The avidity with which he absorbed the new experimental work and theories about crystal structure in his old age is evidenced by his latest publications.

Devotion to academic duties and to the *Zeitschrift* left comparatively little time for travel, but Groth made mineralogical expeditions in France and Italy. In 1904 he visited England for the British Association meeting and made a tour in Wales. In Great Britain his position in the scientific world was fully appreciated fifty years ago when he was elected an honorary member of the Mineralogical Society. He was afterwards elected foreign correspondent (1895) and foreign member (1900) of the Geological Society (and received its Wollaston Medal in 1908), and foreign member of the Royal Society in 1911. He received the Hon. Sc.D. degree from Cambridge in 1904.

The present writer has a vivid recollection of Groth as an active young professor at Strasbourg in 1881; energetic and busy with his class and his collection, but always accessible and ready to help and inspire the little group of eager research students who worked in his laboratory. He always impressed them as a strenuous worker, a great teacher, and a most genial, sympathetic, and loyal friend.

H. A. M.

MR. THOMAS BAIRD.

A TRAGEDY on the Cairngorms has deprived the University of Glasgow of two brilliant and promising men, of whom one, Thomas Baird, was on the staff of the Geological Department. He attracted attention early in his geology course by his quickness as an observer, his intellectual ability, and his enthusiasm as a student. His early death at the age of twenty-two years has prevented him completing any of the research work on which he had entered, but he had done enough to give promise of great success. He has recorded some sections exposed in the foundations of the new buildings of the National Bank, and described the glacial sands there interbedded with the boulder clays. He had begun the investigation of volcanic necks at Yieldshields Hill, near Carluke, and was working out their inclusions with some help from Dr. Tyrrell.

Baird's special interest was in mountain structure, and he was studying some Dalradian rocks in the Grampians to the east of Kinloch Rannoch, of which the correlation is in doubt. Mr. Baird's interest in mountain geology led him to take every opportunity of training as a mountaineer. He had made some winter ascents and gained experience in ice-climbing. It was his ambition ultimately to explore some of the Asiatic mountain ranges of which the structure is still unravelled.

With this end in view, Baird arranged the recent excursion to the Cairngorms in order to gain further experience of mountaineering under winter conditions. He and his companion, Hugh Barrie, a medical student and graceful poet, were both thoroughly competent for the expedition. They appear to have spent three nights at the Corrour bothy between Ben Macdhui and Cairn Toul, and from such clues as are available they probably gained the summit of Braeriach on the return route to Aviemore on Sunday, Jan. 1. Some accident must have happened there, for Baird's left hand was injured as if he had caught hold of some rock or rough ice. He probably exhausted himself either in the effort to help Barrie to shelter, or, as appears more likely, when trying to find his comrade after their separation by the accident. Baird had reached the floor of Glen Eunach, and there, caught in a furious blizzard, collapsed on the roadside a few hundred yards from a hut. He was found next morning, but died before help could arrive from Aviemore.

News and Views.

IN a supplement to this issue we publish an article by Prof. de Sitter in which a comparison is made of the time as determined by the rotation of the earth, the revolution of the moon round the earth, and of the inner planets round the sun. The application of the theory of gravitation and the laws of motion to the various bodies shows that equal intervals of time determined by one body are not exactly equal according to the others. The application of the laws of dynamics is complicated by the fact that the earth is not a rigid body and that tidal friction is slowly decreasing the rate of the earth's rotation and at the same time that of the moon's revolution. It is not possible to compute the numerical coefficient exactly, but work by Jeffreys on the tidal friction in narrow seas gives a coefficient of the right order of magnitude. Prof. de Sitter finds that the observations are best explained if the coefficient for the three intervals, before 1745, 1745–1870, after 1870, are approximately in the ratio 2 : 1 : 3. It is, however, difficult to explain why the coefficient should have altered to this extent. Tidal friction can only slow down the earth's rotation, while observations of the moon and planets indicate that at times this rotation is accelerated. This can only be done by reduction of the earth's moment of inertia. Prof. de Sitter finds that the reduction of the whole mountain range of Central Asia to sea-level would have produced only one-quarter of the change in the length of the day which observations of the moon indicate took place in the year 1918, but that an alteration of the earth's radius by five inches would suffice. Both explanations almost appear to call for observable effects on the earth itself.

EXPRESSED in time, observations of the moon indicate that the earth's period of rotation altered by 0·00339 sec. either suddenly or in the course of a few months in the year 1918. This means that the earth's rate of rotation altered by approximately 1 part in 25 millions. Prof. de Sitter raises the question whether this is sufficiently large to be tested by an actual clock. The free pendulum clock, Shortt 3, installed at Greenwich, has shown a great advance on all previous clocks; for example, its daily rate has remained constant for more than six months to the order of 0·001 sec., except for a secular term which altered the daily rate by 0·032 sec. in 100 days. This coefficient, as well as the rate, has to be determined from astronomical observations. It corresponds to a slow lengthening of the invar rod and is probably decreasing with time. The clock has, however, a rather large temperature coefficient, namely, about 0·007 sec. daily per 1° C. The cause of this is unknown, but it may be due to the impulse varying with the temperature and consequently changing the arc of vibration. To produce a change of 0·007 sec. in the daily rate the semi-arc, at present about 55′, has to alter only 10″, a quantity too small to be observed accurately with the Greenwich clocks, but possible with later ones.

THE election of Prof. D'Arcy W. Thompson as president of the Classical Association for this year calls for the congratulations of his scientific friends. Not all men of science are devoid of some tincture of letters, as the pages of NATURE testify, but it is sometimes hinted that it is not hard to pass for a scholar in their company. Prof. Thompson's election shows, however, that he is esteemed as a scholar by literary men. He is, indeed, peculiarly fitted to link the older with the newer humanities. His contributions to the history of Greek science—his "Glossary of Greek Birds," his translation of Aristotle's "Historia Animalium," and his Herbert Spencer Lecture on "Aristotle as a Biologist," to name only a few—are well known and valued. On the other hand, he brings to his scientific work not only a polished style but also a sense of the historic background of knowledge which illuminates even the pages of reports on fishery statistics. His "Growth and Form" showed that he could handle and correlate, as few men can, the results of research in the most diverse branches of modern science. Prof. Thompson's love for the classic literatures is inherited, and those who have read the "Daydreams of a Schoolmaster" will know how it would have gratified the author could he have seen his son in the position to which he has just been elected.

AN article from the *Times* correspondent at Delhi, in the issue of Jan. 12, conveys the welcome news that a great new meteorological observatory at Poona is to be brought into use this summer, thus carrying into effect a scheme proposed in 1924 for transferring the headquarters of the Indian weather department thither from Simla. The difficulties that have led to the transfer are not limited to the tropics. On one hand, it is vital that the routine work of daily forecasting and of administration shall be well carried on, for it is on performance of these tasks that revenue depends, and with that the chance of scientific progress. Further, there is a material gain of efficiency if the staff can be collected into the same station, facilitating co-operation as well as access to laboratories and libraries. There is, therefore, a tendency for the ablest men to gravitate to headquarters. But Simla cannot employ kites because winds are too light, or instrument-carrying balloons because of the wild mountain regions in which they would be lost: so experimental examination of the physical processes of weather can scarcely be effected there, and bringing up an officer from a provincial observatory very seriously reduces his chance of advancing knowledge and of keeping in living contact with science. The remedy adopted by the department in India has been to give up the advantage of being at the seat of government and to transfer its headquarters to Poona, where upper air work is possible and monsoon conditions, unlike those of the western Himalayas, are representative of India. Poona has the further advantages of a good climate and of proximity to Bombay, so that closer relationships can be maintained with shipping and commercial interests.

THE *Times* correspondent says, however, that the object of the new observatory is "special research work with a view to elaborate and accurate forecasting of the south-west monsoon." Also "The Meteorological Department . . . is now able regularly to forecast in mid-October the quantity of rainfall in Northern India in the next five months. The indications are given to within a fraction of an inch, and during twelve years wherever the system has been followed it has never proved fallacious." On reading this surprising account, it is natural to inquire into the recent success of the method, and we find Mr. Field in his forecast of Jan. 6 last, after rightly deprecating undue confidence, saying that the high-level winds were "about normal in character." The total actual precipitation, as described on June 27, was, however, not normal but "in moderate defect." Again, in the previous year the high-level winds were "stronger than usual"; and the total actual precipitation was not in excess as it should have been, but "in slight defect." In spite of this lack of perfection, we are convinced that upper-air data promise to be of great value for seasonal forecasting after twenty or thirty years of data have been accumulated; but friends of the department should lay stress on the value of the upper-air work done at Poona for aerial navigation and daily forecasting, rather than arouse expectations of an early revolution in methods of seasonal prediction. Confidence in long-range forecasts can only be built up slowly, and is more easily lost than won.

THE award of the Progress Medal of the Royal Photographic Society to Dr. S. E. Sheppard in recognition of his researches and publications, which have resulted in important advances in the science of photography, will be generally welcomed. Dr. Sheppard is still, in the modern sense, a young man, whose name first came into prominence in connexion with the extended series of researches in photographic subjects, carried out in conjunction with Dr. Mees. The results were published in the *Photographic Journal*, in the *Proceedings of the Royal Society*, and in the *Journal of the Chemical Society*, and were then collected, together with additional work, and published in 1907 as a book entitled "Investigations on the Theory of the Photographic Process." Dr. Sheppard is also the author of the volume on "Photochemistry" in the series of text-books on physical chemistry edited by Sir William Ramsay. Dr. Sheppard was elected to an 1851 Exhibition research scholarship and proceeded to Germany for further study. Shortly after returning to England he was offered a position in the Research Laboratories of the Eastman Kodak Company, Rochester, N.Y.

SINCE taking up his duties at Rochester, where he is assistant director of research, Dr. Sheppard has been responsible for researches covering many phases of the photographic process, which culminated comparatively recently in his important discovery of the rôle played by sulphur compounds contained in gelatin in conferring sensitivity on the silver halide grain. In addition to the books already mentioned, Dr. Sheppard has been responsible for two others, namely, "The Silver Bromide Grain of Photographic Emulsions," and "Gelatin in Photography," vol. 1, published by the Eastman Kodak Company, and has done valuable work in connexion with the electro-deposition of rubber. Previous recipients of the Progress Medal have included Sir William Abney, Dr. J. M. Eder, Prof. Gabriel Lippmann, Ferdinand Hurter and Vero C. Driffield (jointly), Mr. Alfred Watkins, A. Lumière et ses fils, Dr. C. E. K. Mees, Mr. William B. Ferguson, and the present president of the Royal Photographic Society, Mr. F. F. Renwick.

ON Tuesday, Mar. 20, H.M. the King will open the eastern block of the new buildings of the Science Museum at South Kensington. First-formed in 1856, the collections have occupied various buildings, but now for the first time they are shown in one designed for this purpose, though about a quarter of the collections still remain in buildings which were originally constructed for the exhibition of 1862. In 1898 Parliament voted £800,000 for completing the Science and Art Buildings at South Kensington, and in 1908 the Victoria and Albert Museum was opened by H.M. King Edward VII. As nothing had so far been done for the science collections, a number of men eminent in science and in technical industry strongly urged the need for action in the matter. Sir Henry Roscoe headed a deputation fully representative of science and its applications, which was sympathetically received by the President of the Board of Education, and in the following year the President appointed a committee, of which Sir Hugh Bell was chairman, to inquire into the Science Museum and to report upon its needs. This Committee recommended that new buildings should be erected on the existing site, which should ultimately extend from Exhibition Road to Queen's Gate.

IT is the eastern block, the first instalment of this scheme recommended by the Committee, which is to be opened in March, doubling the exhibition area of the Museum. Though the space available is still considerably less than that which the Committee laid down as being immediately needed, it has made it possible to develop the collections extensively, and to improve very greatly the setting out and exhibition of them. The result of this is reflected in the greatly increased numbers of visitors, of whom more than 709,000 visited the Museum during 1927 as compared with 450,000 in 1925. The new galleries are exceptionally well lighted, and the provision of compressed air and electricity in each gallery makes it possible to show objects in motion or specially illuminated at any point in the Museum.

IN February 1927 the Government of Queensland appointed a Land Settlement Advisory Board of three members, with the powers of a Royal Commission, to inquire into and report upon various questions in connexion with the administration of land leased for grazing sheep in Central and Western Queensland, and "generally what action should be taken by the Government to further develop the wool industry in Queensland." In the Board's report, which has been presented by the Premier to the Queensland Parliament, it is stated that the total number of sheep in

Queensland remained almost the same (20 millions) between 1891 and 1925, in spite of the fact that in the same period the population of the State increased by 109 per cent. and the railway mileage by 165 per cent. Owing to the severe drought that has prevailed over much of the sheep country since 1925, it is estimated that the number of sheep is now only 14 millions. Since, during the last five years, wool constituted 60 per cent. of the State's exports, it is obvious that the prosperity of the industry is of vital importance to Queensland.

THOUGH none of the members of the Board were scientific men, it is gratifying to find that a section of the report is devoted to the advocacy of scientific research. It is stated that "the valuable results obtainable from the practical application of science to industry have already been demonstrated sufficiently in Queensland to urge all authorities to further efforts. The banana bunchy-top investigations and the chemical and biological agencies for prickly pear destruction are instances of scientific endeavour of first-rate importance to this State. In each of these investigations the scientists of the University of Queensland played their part. Another field of endeavour is now presented to scientists in stemming the annual wastage in the wool industry." Among the problems which are mentioned as requiring scientific investigation are the provision of suitable stock licks for different types of country, the effect of artificial feeding on wool production, the effect of different grasses on the quality of the wool, the varying mineral and protein contents of pastures on the different geological types of country, the effect of overstocking on natural grasses, particularly as regards their re-growth, and the prevention of losses due to blow-fly, worms, and other parasites and diseases. It is stated that the Premier of Queensland has offered to the Commonwealth Council for Scientific and Industrial Research an area of about 25,000 acres of land in Central Queensland, free of rent for any term desired, to be held in trust as a central scientific station for investigations on the above and kindred subjects, and the hope is expressed that the offer will be accepted either in whole or in part.

WITHIN a fortnight from the date of his first dispatch on the season's work at Ur, Mr. Woolley is able to chronicle in the *Times* of Jan. 12 a further discovery of almost sensational interest which throws an entirely new light upon the customs and religious beliefs of the Sumerians. Although the body of the king has not been found in the Royal Tomb now being excavated, as probably it was plundered at an early date, a large number of objects interred at the time of the burial for his use have been unearthed. Among these are a harp, largely composed of wood, the form of which has been recovered by the use of plaster to fill up the cavities left by the decay of the wood; a chariot, on the rein ring of the pole of which was a wonderfully realistically executed donkey in silver; a gaming board; a clothes' chest; and piles of copper bowls and tumblers. The remarkable feature of the burial, however, is that, scattered among these relics are the remains of the king's attendants, evidently lying as they fell when sacrificed for his service in the next world. The harper is crouched near his harp, two asses lie at the chariot pole, and with them their three grooms; and by the clothes' chest is an officer of rank, as shown by his ornaments, possibly the Keeper of the Royal Robes, and other attendants. In a trench lie thirteen bodies, of which two are those of children, the rest women, no doubt the members of the Royal Harem. Mr. Woolley is of the opinion that this form of burial, accompanied by the sacrifice of the Court attendants, must be regarded as a survival, as there are no evidences of similar sacrifices to be found in the graves of common people.

ON Feb. 14 the Royal College of Surgeons of England celebrates the bicentenary of John Hunter, who may be described as the patron saint of the College. Hunter left one of the most remarkable collections of anatomical preparations and natural history specimens ever assembled by one man. In 1800, seven years after his death, this collection was purchased by Government and handed over to the College of Surgeons in trust. The Hunterian Collection forms the basis of the great museum now housed by the College in the south side of Lincoln's Inn Fields, but the additions made under a long line of conservators, which includes Owen, Quekett, and Flower, now overshadow the original collection. There is a doubt as to the exact date of Hunter's birth, but as he celebrated it on Feb. 14 the Hunterian oration given in his memory every alternate year has always been given in the theatre of the College on this date. On the present occasion the oration is to be delivered by Sir Holburt Waring, surgeon to St. Bartholomew's Hospital, and a former Vice-Chancellor of the University of London. A lecture on the "London Homes of the Hunters" will be given by Mr. G. C. Peachey. A special exhibition of specimens will illustrate John Hunter's chief discoveries. Visitors will also have an opportunity of examining his portraits, busts, published works, manuscripts, and personal relics.

IN a letter to the Editor, Prof. Henry J. Spooner discusses our comment in the issue of Dec. 24, p. 928, on his paper in the *Society of Industrial Engineers' Bulletin* (vol. 9, No. 9), in which he stated that the economic loss through the effects of noise is estimated at £50,000,000. We asked how this figure was obtained. Prof. Spooner states that men of affairs "have their capacity for clear thinking without a doubt perceptibly weakened by the incessant if unconscious strain upon the nervous system" caused by noise, and he says he has had countless letters from mental workers explaining how their health and work suffer through working in a noise. Such remarks, though true as personal expressions of opinion, do not, however, constitute scientific proof. The one piece of research quoted, that of Dr. Laird, would seem to be suggestive rather than conclusive. The control group is always necessary. If one has a personal interview with all the workers in and near a noisy room and inquires about noise among other conditions of work, one does not get a uniform reaction; some dislike it, some are indifferent, some prefer it. There are heads of departments, creative workers of all kinds, as well as the actual noise producers, who are frankly surprised at the idea of their work being affected by noise. To say it must be unconsciously affected is again opinion, not evidence. In the interests of those who either are, or think they are, detrimentally affected, let us minimise noise, but the proof of its effect is not easy.

GAS undertakings deserve more publicity than is usually accorded them concerning the extent and intricacy of the organisations necessary to maintain an unfailing service of their chief products, and to provide an important supply of the great number of other materials in everyday industrial demand. The consumer's end of the pipe-line is so easily manipulated, day or night, in war and peace, strike or lock-out, with the same anticipated result, that it is not surprising that public attention should be focussed more frequently on cost than on supply. For use on the occasion of the visit of the Science Masters' Association to the Chief Offices, the Central Store, and the Fulham Works of the Gas Light and Coke Company on Jan. 6, the Company prepared an illustrated brochure giving a short account of its activities, and briefly describing the sections visited.

THE Gas Light and Coke Company received its charter so long ago as 1812; its authorised capital is now more than £40,000,000, its employment roll about 20,000, and its area of supply to 1,250,000 consumers is 265 square miles, extending from Windsor Great Park to some miles east of Epping Forest. Every year some 2¼ million tons of coal—mostly borne direct by the Company's own fleet—are required. Of the thirteen works, those at Beckton are responsible for the output of about 40 per cent. of the gas produced, whilst those at Fulham, which are probably the oldest in London, are now representative of the most modern practice in gas-works construction, having a capacity (shortly to be largely increased) of 17½ million cubic feet of 500 B.Th.U. quality (*i.e.* 87,500 therms) a day, and treating 900 tons of coal daily on an area of 30 acres. Usually 40,000 tons of coal is held in stock at Fulham; the coal gas, maintained at a constant quality with water-gas of variable composition, is conveyed by means of more than 100 miles of high-pressure mains (at pressures of the order of 3 lb. per sq. in.) to convenient storage centres, and thence in 3700 miles of supply mains at pressures of about 4 in. water gauge. The brochure gives an account also of the housing of the experimental plant and the various research laboratories; it describes the training and welfare work, and refers to the measures which have been taken to give effect to a spirit of copartnership which exists between the Company and its employees.

DR. J. STEPHENSON, lecturer in natural history in the University of Edinburgh, has been appointed editor of the "Fauna of British India" series in succession to the late Sir Arthur Shipley.

DR. EDWARD RAY WEIDLEIN, Director of the Mellon Institute of Industrial Research, University of Pittsburgh, has been re-elected president of the American Institute of Chemical Engineers and will therefore serve in this office during 1928.

DR. MAX WOLF, Director of Heidelberg Observatory, distinguished especially for his originality and activity in observational astronomy, has been elected an honorary member of the American Astronomical Society. The constitution of the Society permits the election of one honorary member at each annual meeting, but no election has been made since 1924.

AT a meeting of the Quekett Microscopical Club, held on Jan. 10, Mr. E. M. Nelson, Dr. A. Mann, and Dr. Karl Viets were elected honorary members. Mr. Nelson was president of the Quekett Club from 1893 until 1895, and also president of the Royal Microscopical Society from 1897 until 1899. He is the author of numerous papers dealing chiefly with the practical optics of the microscope and microscopical technique, which have appeared in the *Journal of the Royal Microscopical Society*, the *Journal of the Quekett Club*, and in the *English Mechanic*. Dr. Mann, of Washington, D.C., is well known as an authority on Diatoms; and Dr. Viets, of Bremen, has done a large amount of original work on the Hydracarina and Halacaridæ.

THE British Empire Cancer Campaign announces an international convention on cancer research to be held under its auspices in London next July. Of the value of such international meetings, especially on the personal side, there can be little doubt, though there seem to have been rather many lately on this particular topic, and the amount of time which those who are actively engaged in cancer research can profitably spend in travelling to meetings across the world obviously has its limits. In this case we are glad to note that none of the considerable expense of the convention will fall on the funds of the Campaign, owing to a generous donation from Sir Richard Garton.

THE Gold Medal of the Royal Astronomical Society has been awarded to Prof. R. A. Sampson, Astronomer Royal for Scotland, for his theory of the four great satellites of Jupiter. This extensive work is contained in three separate memoirs in the *Harvard Annals* and the *Memoirs of the Royal Astronomical Society*. With the tables to which the theory is reduced, it completes a self-consistent revision of the whole problem of the four great satellites. A bronze (Jackson-Gwilt) Medal has been awarded (1) to Dr. W. H. Steavenson, for his work on faint variable stars and on the Herschel instruments; and (2) to Mr. W. Reid, of Cape Town, for his discovery of six new comets.

THE seventh International Congress of Photography will be held in London on July 9–14, under the auspices of the Royal Photographic Society. There will be three sections: (1) scientific and technical, (2) pictorial photography, (3) bibliography and record work; the scientific and technical section will be further subdivided into groups dealing with theoretical aspects, photographic practice, scientific applications of photography, and industrial and special applications. Papers for the Congress, accompanied by abstracts, both in duplicate and typewritten, must be submitted to the honorary secretary to the organising committee, Dr. W. Clark, The Science Museum, South Kensington, London, S.W.7, before June 1.

An exhibition indicating the possible utilisation of Overseas Empire timbers in industry will be held at the Exhibition Pavilion of the Imperial Institute, South Kensington, on Feb. 3–April 30. This exhibition is the second of a series arranged to direct attention to specific resources of the Empire, with the object of increasing the usage of Empire raw materials in Great Britain. Samples of selected timbers from some of the Dominions and Colonies will be shown in conjunction with the articles which can be made from them. An important feature will consist of exhibits illustrating the work carried out at the Imperial Forestry Institute, University of Oxford; the Forest Products Research Laboratory (Department of Scientific and Industrial Research) at Princes Risborough; and at the Imperial Institute.

The council of the Geological Society has this year made the following awards: Wollaston Medal to Dr. D. H. Scott, lately honorary keeper of the Jodrell Laboratory, Royal Botanic Gardens, Kew, in recognition of the value of his researches in fossil botany; Murchison Medal to Dr. J. J. Sederholm, Director of the Geological Commission of Finland, in recognition of his researches in petrology, especially of the granites and gneisses of the pre-Cambrian complex of Fennoscandia; a Lyell Medal to Prof. S. H. Reynolds, C. Wills professor of geology in the University of Bristol, in recognition of the value of his researches in the stratigraphy of the Palæozoic rocks, and in vertebrate palæontology; a second Lyell Medal to Dr. W. D. Lang, keeper of the Department of Geology in the British Museum, for his researches in stratigraphy and palæontology, especially with reference to the Bryozoa; the Wollaston Donation Fund to Mr. James Wright, for his researches on the Crinoidea of the Carboniferous Limestone of Scotland; the Murchison Geological Fund to Dr. George Slater, in recognition of the value of his researches in glaciology; and the Lyell Geological Fund to Mr. Ben Lightfoot, for his researches on the economic geology of Southern Rhodesia.

The natives of Teheran (Persia) have discovered a new, if rather primitive, method of making ice in the winter months and storing it for summer use, according to a writer in *La Nature* for Jan. 1. Long ponds, running east and west, are dug in the earth and filled with water. Due to the slight night frost, a very thin coating of ice forms. The next night this ice is watered, and the layer of ice increases, until it gradually attains a thickness of about 16 inches. The ponds are protected on the south side by high earth walls to prevent the sun getting to the ponds even at its maximum elevation. The ice thus formed is broken up and stored in blocks in large galleries dug in the earth and separated into compartments, broken ice being placed between each block. When the summer comes, the ice blocks are broken up and retailed in small portions. The insulation provided by the storage galleries is stated to be sufficient to keep the ice without appreciable loss for two years.

From the *Report* for 1926 of the Museums of the Brooklyn Institute (N.Y.), we learn that the Children's Museum has obtained the full-time services of a scout instructor. He gave one day each week to the instruction of the Boy Scouts in their summer camp. More than 6000 Boy and Girl Scouts prepared in the Museum for their tests in nature study. Scout captains use the exhibits for demonstrations. This is only one of many lines along which this little Museum does admirable work in promoting a love of Nature among young people of all classes.

The January issue of the *Journal of the Institution of Electrical Engineers* contains three "Progress Reviews," namely, "Electricity in Mines," by J. A. B. Horsley; "Co-operative Research in 1927," by E. B. Wedmore; and "Electrical Standardization, 1927," by P. Good. These reviews can be obtained in pamphlet form (1*s.* each) from the Secretary of the Institution.

Messrs. Baird and Tatlock (London) Ltd., of 14-15 Cross Street, Hatton Garden, London, E.C.1, have issued a new edition of vol. 1 (Chemistry) of their Standard Catalogue of Scientific Apparatus. This work—it is a work of no small merit scientifically, commercially, and artistically—is intended to be used in conjunction with the other volumes of the Standard Catalogue, namely, vol. 2, Physiology; vol. 3, Biological Sciences; and vol. 4, Physics. The volume just issued is subdivided into nine separate sections, covering respectively laboratory fittings, general equipment, general chemical apparatus, physical chemistry, industrial chemistry (two sections), meteorology, books, and chemicals. The preface is dated October 1927, so that although such a catalogue of between eleven and twelve hundred large pages must of necessity take months to prepare, the prices which are quoted have yet had but little time in which to undergo their inevitable fluctuations. The illustrations are particularly good, and this fact, together with the comprehensiveness with which the whole publication has been conceived, makes the catalogue a noteworthy addition to the library of any educational institution or industrial laboratory in which experimental chemistry and the allied sciences are pursued. Descriptive paragraphs concerning the operation of the more complex and less well-known pieces of apparatus are a welcome feature. These paragraphs sometimes attain almost monographic proportions; the article on the theory and use of the polariscope, for example, consists of two closely printed pages, with diagrams, and even a reference to a paper in the *Berichte*, whilst that on the determination of hydrogen ion concentration covers three pages. Many new pieces of apparatus not hitherto catalogued are included; even more recent additions to the chemist's armoury will be dealt with from time to time in separate leaflets. The whole publication is adequately indexed, with cross-references to the companion volumes.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A gas engineer and general manager under the Rotherham Corporation—The Town Clerk, Rotherham (Jan. 25). An inspector under the Ministry of Agriculture and Fisheries for the purposes of the Diseases of Animals Acts, 1894–1925—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Jan. 30). Assistant Veterinary Inspectors under the Surrey County Council to carry out duties under the several Acts and Orders relating to (1) Milk and Dairies; (2) Diseases of Animals; and (3) such other veterinary duties as the Council may require—The Clerk of the County Council, County Hall, Kingston-on-Thames (Jan. 30). A junior scientific officer under the directorate of scientific research of the Air Ministry primarily for work in the engine research department of the Royal Aircraft Establishment, South Farnborough—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (Feb. 11, quoting A.256). A lecturer in mycology at the Imperial College of Tropical Agriculture, St. Augustine, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 14 Trinity Square, E.C.3 (April 1). A senior lecturer in physical and inorganic chemistry in the University of Melbourne—The Registrar, The University, Melbourne, Victoria (April 23). A principal of the Australian School of Forestry, Federal Capital Territory, Canberra—The Secretary, Department of Home and Territories, Canberra, Australia (April 30). An additional lecturer in zoology at the Ceylon University College, Colombo—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S.W.1. An assistant bacteriologist at the Wellcome Bureau of Scientific Research—The Secretary, Wellcome Bureau of Scientific Research, 26 Endsleigh Gardens, W.C.1. A technical laboratory assistant at the Millport Marine Station of the Scottish Marine Biological Association—The Secretary, S.M.B.A., 88 Bath Street, Glasgow. Teachers of Siamese and of Tibetan at the School of Oriental Studies—The Secretary, School of Oriental Studies, Finsbury Circus, E.C.2.

ERRATUM.—A correspondent points out that the late Mr. W. H. Dines was at Corpus Christi College, Cambridge, and not at Christ's College, as was stated in our issue of Jan. 14, p. 65.

Our Astronomical Column.

LARGE METEOR ON JAN. 9, 11^{h} P.M.—Mr. W. F. Denning writes: "This very large meteor was seen by an observer when motoring about 6 miles east of Birmingham. The terminal portion of its flight was from near the star Sirius vertically to the horizon. The object was much brighter than Venus at its best, and the nucleus threw off a dense train of sparks at the end. The same meteor was noticed from Ilford, Essex, where the path was recorded as moving from just below Rigel and κ Orionis in a direction towards the western horizon. It was very brilliant, and gave an outburst of sparkling material.

"Further observations will probably come to hand, but it appears that the fireball must have radiated from near the bright star Sirius and that its height was about 63 to 20 miles over a line directed from south to north over the English Channel to its finishing stage over Hampshire. Further data are, however, desirable, particularly from observers near the south coast of England."

THE RECENT GREAT COMET.—Many reports are coming to hand from America and elsewhere, that show what an extremely fine comet this must have been. Its magnitude rose at least to -6; some estimates make it -10. Its tail was at least 8° long: it would doubtless have been more if it could have been seen on a dark sky.

Dr. Slipher reports in a *Daily Science News Bulletin*, issued by Science Service, Washington, that its spectrum was continuous, with no bright lines, indicating that the light was mostly reflected sunlight; but an appreciable amount of lower temperature radiation was present. The nucleus was small, and varied from a circular to an elongated shape. Jets and envelopes were present on the sunward side of the nucleus.

The spectroscope indicated a motion of recession from the earth of 60 miles a second (exact time of observation not stated). The actual rate of recession between Dec. 20 and 21 was 54½ miles a second, which is a good agreement.

The following orbit by Dr. A. C. D. Crommelin is from a combination of observations ranging from Dec. 3 to 20:

$$\begin{array}{ll}
\multicolumn{2}{l}{\text{T 1927 Dec. 18·008 U.T.}} \\
\omega & 46^\circ\ 9{\cdot}7' \\
\Omega & 76\ \ 25{\cdot}2 \\
i & 85\ \ 27{\cdot}2
\end{array}\left.\vphantom{\begin{array}{l}a\\b\\c\end{array}}\right\}1927{\cdot}0$$

$$\log q \quad 9{\cdot}2365$$

The earliest known observation of this comet (a day before that of Mr. Skjellerup) was obtained by Mrs. K. Botes at Fraserburg, Cape Province, on the morning of Dec. 2. She slept on a verandah facing south-east and observed the comet from her bed. It was low in the south-east about dawn. Other independent discoverers were Mr. Ross Fitchet at Grahamstown, Dec. 5; Mr. Maristany at La Plata, Dec. 6; Mr. Chidambara Iyer, Kodaikanal, Dec. 15.

Dr. A. C. D. Crommelin has deduced the following elliptical orbit of comet Schwassmann-Wachmann from Bergedorf observations on Nov. 15, Dec. 4 and 28.

$$\begin{array}{llll}
\multicolumn{4}{l}{\text{T 1925 May 10·9230 U.T.}} \\
\omega & 359^\circ\ 56'\ 13{\cdot}7'' & & \log a \quad 0{\cdot}8090646 \\
\Omega & 322\ \ 35\ \ \ 2{\cdot}2 & \}\,1927{\cdot}0 & \log q \quad 0{\cdot}7403755 \\
i & 9\ \ 25\ \ 37{\cdot}0 & & \log n \quad 2{\cdot}3364097 \\
\phi & 8\ \ 24\ \ 43{\cdot}0 & & \text{Period } 16{\cdot}35298 \text{ years.}
\end{array}$$

The orbit lies wholly between those of Jupiter and Saturn; the comet has the largest perihelion distance and the smallest eccentricity of any known comet. In consequence of the small eccentricity, the date of perihelion is difficult to determine and is still very uncertain.

Research Items.

ANTHROPOMETRY IN FORMOSA.—A valuable addition to our knowledge of the aborigines of Formosa is made by Akira Matsumura and Etsuzu Miyauchi in a contribution to the *Proceedings of the Imperial Academy of Tokyo*, vol. 3, in which they give a summary of anthropometric measurements carried out by them under government auspices. The subjects measured were all men between the ages of twenty-three and forty-five years. The present communication deals with stature, cephalic index, and nasal index only. With the exception of the Ami, who inhabit the plain on the south-eastern coast, and the Yami, who live on the island of Botel Tobago, all the tribes belong to the central mountainous area. In stature the mean descends in the order Ami, Tayal, Vunam, Paiwan; in head-form the index in ascending order is Ami, Tayal and Vunam, Paiwan; nasal index, again ascending, Tayal, Paiwan, Ami. Generally speaking, proceeding from north to south, the mountain tribes become lower in stature, broader in the head and wider in the nose; but the Ami of the south-eastern plain have the greatest stature and are the most dolichocephalic and chamæprosopic of all the aborigines. Comparing them with the Philippine Islanders, the aborigines of Formosa resemble closely the Bontoc and Tagai tribes. The ranges of the means are: stature, 157·14 (Paiwan) to 165·14 (Ami); cephalic index, 76·42 (Ami) to 81·30 (Paiwan); nasal index, 75·78 (Tayal) to 86·15 (Ami).

PHILIPPINE SEA-URCHINS.—No. 100 of the *Bulletin of the United States National Museum* consists of Dr. Th. Mortensen's report on the Cidaridæ collected by the *Albatross* during the Philippine expedition of 1907–10. The delay has enabled the author to utilise the knowledge and experience gained on his own later expeditions to the Pacific and the Malay Archipelago. The cidarid sea-urchins here described fall into ten genera, of which Rhopalocidaris, with club-shaped secondary spines, and Psilocidaris, with slender primary and secondary spines, are new. Cyrtocidaris also is founded as a new subgenus of Goniocidaris. Psilocidaris links this form with Aporocidaris, of which the affinities were previously obscure. Of the twenty-seven species and varieties described, six species and seven varieties are new, but, though the descriptions and figures are worthy of his reputation, Dr. Mortensen leaves to some future worker the task of constructing diagnoses. The number of cidarid species now known from the Malayan and Philippine seas exceeds forty, and since many are represented by single specimens, the number of species will doubtless be increased. This is in strong contrast with the eight or possibly ten from the West Indies and the three or four from the whole of the north-east Atlantic. Collectors are warned against pickling echinoids with crinoids, since the pigment from the latter stains the other contents of the jar.

A NEW ECTOPARASITIC TREMATODE.—A new species of Epibdella was found on fishes in the New York Aquarium. It had been introduced into the tanks by a Pacific puffer (*Spheroides annulatus*) from Southern California, but the eyes of the spade fish (*Chætodipterus faber*) and of various species of angel fishes (Angelichthys and Pomacanthus) became infected. The Pacific puffers have eyelids which can be closed over the eyes, so that the worms can adhere within the conjunctival sac, and several worms may be present therein, but fewer are found on the eyes of the other fishes. The cornea of infected fish is pierced, and in about three weeks the eye is destroyed. The largest worms are about 5 mm. long and 3 mm. wide. Dr. G. A. MacCallum (*Zoopathologica*, Sc. Contribs. New York Zool. Soc. on the Diseases of Animals, vol. 1, No. 8, 1927) gives a description, with figures, of the external features and internal structure and of the eggs, and points out how this new species of Epibdella differs from those previously described.

BIOLOGICAL SIGNIFICANCE OF MYCORRHIZÆ.—Present-day opinion on the significance of mycorrhizæ veers all the way from a belief in the truly symbiotic nature of the association of the root and fungus concerned to an investing of the fungus with a purely parasitic rôle. Recent contributions to the subject come from Kôki Masui (*Memoirs of the College of Science, Kyoto Imperial University*, Series B, vol. 3, No. 2) and Lewis Knudson (*New Phytologist*, vol. 26, No. 5). After a detailed investigation of the ectotropic mycorrhizæ of woody plants, Masui defines two groups of mycorrhizal fungi: obligate forms such as *Hydnum affine, Cantharellus floccosus, Polyporus leucomelas, Armillaria caligata*, and facultative forms such as Boleti. He considers the former group as being truly parasitic, the latter group as 'hemi-symbiotic.' From microchemical observations Masui concludes that the growing points of normal roots contain large amounts of amino-acids and sugar, but these nutrients are gradually depleted by the fungi, until, in old mycorrhizæ, no nutrients are found in the root tissues. This may explain to a large extent the inhibition of root growth after infection. The roots, which still contain tolerable amounts of these nutrients, can grow further, pushing aside the fungoid mantle. On the other hand, the facultative mycorrhizæ formers supply a larger amount of phosphorus to the host plant than the uninfected root can normally absorb, whereas in the obligate ones the relation is just the opposite. Prof. Knudson severely criticises Constantin's idea of obligate symbiosis in the case of orchid mycorrhizæ. The work of the former clearly shows the dependence of the orchid embryo on soluble organic matter, and the investigations indicate that the capacity for synthesising food is lacking in the embryo. Given suitable organic food material and a hydrogen ion concentration in the medium sufficient to retain the iron in solution, orchid seeds germinate asymbiotically. The orchid fungus may be useful in making insoluble food material available for the root and in regulating the hydrogen ion concentration of the medium. Constancy of association of orchid root and fungus is taken as merely indicating the wide distribution of the orchid fungi and the readiness with which the orchid embryo and root can become infected.

POST-GLACIAL MOLLUSCA OF GENEVA.—Starting with a study of the hitherto much neglected post-glacial deposits of the Geneva basin, Dr. Jules Favre found that their elucidation required a thorough knowledge of the recent molluscan fauna of the area; and having attained this, he has now embodied the results of his researches in a most valuable monograph on "Les Mollusques post-glaciaires et actuels du basin de Genève" (*Mém. Soc. Phys. Hist. Nat. Genève*, vol. 40, fasc. 3). The greater part of the work (which runs to more than 260 pages) is devoted to a systematic description of the genera and species with their occurrences all most carefully set forth. Especial attention has been paid to that difficult group of little bivalves, the Pisidia. Here the specific descriptions of the several forms are given first and clearly illustrated by admirable and useful outline drawings of the essential features of the hinges on which the determination of them depends, while the species occurring in the district are then gone over seriatim and their local distribution and variations discussed. The biological aspect of the fauna is not dwelt on, but the ecological is dealt with: the association of species, their vertical and bathymetrical distribution being fully treated. The description of the various post-glacial deposits and their fossil contents, which are considered to date back in age to the Upper Magdalenian, form the rest of the work. A useful bibliography and index are appended. The thirteen plates depicting the deviations in form of certain of the more variable species are well reproduced either from photographs or, in the case of the Pisidia, outline drawings by the author. The monograph is one that no worker on the European non-marine mollusca can afford to neglect.

South-Eastern Arabia.—In a paper on "The Physical Geography of South-Eastern Arabia," read before the Royal Geographical Society on Jan. 16, Mr. G. M. Lees stated that Arabia is essentially a great table-land of simple geological structure, so far as Mesozoic-Tertiary tectonics are concerned, and the great monotony of its surface form is the direct result. The high mountain belt of Oman, sticking like a spur into the structures of the Persian mainland, appears as a foreign element on Arabian soil. Three distinctive types of topography constitute the ranges of Oman: (1) a highly dissected limestone country, the best example of which is the northern promontory or Ruus al Jibal; (2) a mountain belt formed of steep, jagged peaks of igneous rock; (3) a limestone plateau country formed of great sheets of horizontal or gently folded limestones. The mountains of Ruus al Jibal are penetrated by many narrow fiord-like inlets up to 9 miles in length and with 20 to 25 fathoms of water up to their heads. They are splendid examples of drowned valleys and indicate a relative depression of at least 1500 feet. Oman proper receives winter rains and Dhofar summer monsoon rain, while the intervening stretch of coast is almost waterless. Dhofar province has a wealth of tropical vegetation. It is the land of frankincense. The nomad tribes of the Samhan hills are non-Arab, and in appearance strongly resemble the Hadandowa tribes of the Sudan Red Sea province. The Sabæan ruins described by Bent were seen. Oman has always been regarded as part of an outer arc of the Persian Zagros system. This arc may exist in fact, but it is of subordinate importance compared with older compressive movements which followed an independent direction. These movements are of Cretaceous age. An intensively folded zone branched off from the Zagros system and passed through Oman. Its last outposts are Masira Island and Ras Madhraka, where it disappears into the Arabian Sea striking in a southerly direction. Argand and Wegener regard the birthplace of India as lying to the east of South Africa; if one assumes a drift of India away from Madagascar, the south coast of Arabia should lie in a region of tension and not of compression.

Tertiary Igneous Rocks of Burma.—The *Transactions of the Mining and Geological Institute of India*, Part 3, May 1927, contain two valuable papers on the volcanic rocks of Mt. Popa (by H. L. Chhibber) and the Lower Chindwin region (by E. S. Pinfold, A. E. Day, L. D. Stamp, and H. L. Chhibber). These two regions, together with the doleritic rocks of the Pegu Yomas, constitute a petrographic province of the circum-Pacific type. The Popa district exhibits the sequence: older andesite (post-Peguan), biotite-andesite, rhyolite, hornblende- and augite-andesites, olivine-basalt; with accompanying tuffs and agglomerates. Possibly volcanic activity ceased only within historic times. The Lower Chindwin volcanics occur as conical hills; as crater-walls surrounding crater-lakes; or as sheets interbedded with Irrawadian sands. Here again there are andesitic types, occurring mainly as sheets; rhyolites and tuffs building the cones; and olivine- and picrite-basalts forming plugs. The rocks of the main volcanic axis of Burma thus present a striking contrast to those of the neighbouring Kabwet area (on the edge of the Shan Plateau), which resemble in a general way the analcitic and titaniferous basalts of the midland valley of Scotland.

Tidal Datum Planes.—A useful monograph on "Tidal Datum Planes" has been issued by the U.S. Coast and Geodetic Survey as *Special Publication* No. 135, the author being H. B. Marmer. Tidal planes, such as those of mean sea-level, half-tide level, mean high water, and so on, form the most convenient datum planes for observations of elevation, because of their simplicity of definition, ease and accuracy of determination, and certainty of recovery, even though all bench-mark connexion be lost. Such planes are the basis of reference in the hydrographic and geodetic work of the United States and in other countries. The monograph provides a working manual for the actual determination of the more important planes, including a discussion of tide gauges, their use and measurement. There is also a detailed discussion of the principles involved and the accuracy attainable in the work.

First-order Triangulation in the United States.—Geodetic operations in the United States for the two years ending Dec. 31, 1926, are recorded by Dr. W. Bowie in *Special Publication*, No. 134, of the United States Coast and Geodetic Survey. The most important task undertaken was the continuation of the readjustments in the first-order triangulation net east of the ninety-eighth meridian. The total length of the arcs of triangulation included in this readjustment is approximately 13,000 miles. The necessity for the work became apparent when attempts were made to fit new work into the previously adjusted arcs. About 1909, Laplace azimuths began to be introduced into all new arcs, and it was evident that they could not be used at the beginning or end of an arc when it started from or ended in an old arc. During the next few years it is proposed to conduct similar work in the eastern half of the country, and also to cut the area into comparatively small circuits, as has been done in the west. The arc of first order triangulation along the Canadian boundary was extended to the Pacific, and among other work of this nature was the continuation of the reoccupation of the old stations in California in connexion with the earthquake investigations. The survey of Alaska makes continued progress.

Fuel Testing in Canada.—The Mines branch of the Canadian Bureau of Mines has issued a report (Ottawa, 1927) on the "Investigations of Fuels and Fuel Testing" carried out in 1925. This somewhat tardy report indicates a considerable breadth of activities of the staff, and although dealing with local problems, some of the work is of general value. There is an analytical survey of cokes sold in Canada as household fuels, balanced by a series of actual tests on various fuels in a typical domestic hot-water boiler. Thermal efficiencies of 70-75 per cent. on the gross calorific value were commonly obtained. The method of tabulating results in comparison with American anthracite is interesting, showing as it does the pre-eminence of Welsh anthracite, while gas and oven cokes also proved more valuable, weight for weight, than the standard. Examination of 46 samples of lubricating oils after use in eight different motor-car engines is reported. The outstanding conclusion was that, contrary to popular opinion, "lubricating oils do not wear out." They become diluted with heavy fractions of petrol and contaminated with dust and carbonaceous matter, but by suitable treatment a new oil, almost as good as the original, may be prepared. The report records laboratory experimental work on the carbonisation of coal and shale at low temperatures.

DAYLIGHT IN BUILDINGS.—*Technical Paper* No. 7 of the Illumination Research Committee of the Department of Scientific and Industrial Research deals with the access of daylight to the interior of buildings. It is to a large extent an account of the present state of our knowledge on the subject, and at a later stage will be supplemented by an account of work done by the Committee. The principal point dealt with in the present paper is the 'sill ratio,' which is defined on p. 1 as the ratio of the internal illumination at a point in a room to "the illumination of a horizontal surface placed on the window sill of the room, all external buildings or other obstructions being supposed removed. . . . This sill ratio can be measured by some forms of portable illumination photometer." It is not made clear in the paper how this measurement can be made without the "external buildings and obstructions" being actually removed.

STREET LIGHTING.—The street lighting of London is a problem the importance of which it is difficult to overestimate. It was discussed in a paper read by W. J. Jones on Nov. 15 to the Public Works, Roads, and Transport Congress. Owing to the changes taking place in the habits of people, both the volume and speed of the traffic are ever increasing. Thoroughfares which were essentially of a residential character are quickly becoming main traffic arteries leading into the heart of London. It is now universally admitted that the eye is the final judge in assessing the effectiveness of street lighting systems. The requirements of good lighting are now well known. In this connexion it is interesting to recall that in 1716 all houses of a rental of £10 or above were required to hang out one or more lanterns with sufficient wick candles lighted therein to last from 6 P.M. to 11 P.M. In State Street, Chicago, the street illumination is very brilliant, owing to the shopkeepers voluntarily taxing themselves for this purpose, the idea being that people will buy more readily when the illumination is brilliant. The author states that it is best to place the light source at a bend in a road at the outside of the bend, as this lights the road surface better. He also recommends placing a lamp with a large reflecting surface behind it at those places where a side road leads directly into a main thoroughfare, and that the London County Council should form a central organisation similar to that in Glasgow, to consider all street lighting problems in the London area.

ANOMALOUS DISPERSION AND ABSORPTION OF ELECTRIC WAVES.—An important paper by S. Mizushima on the anomalous dispersion and absorption of electric waves has recently been received (*Scientific Papers of the Institute of Physical and Chemical Research*, Tokyo, March). By using a thermionic bulb as an oscillation generator for producing waves of short wave-length, the author has made systematic measurements on the anomalous dispersion and absorption of these electric waves. He used a resonant receiver, the circuit being shunted by a small capacity the dielectric of which was to be tested. He found that when distilled water, acetone, benzene, and various mixtures were used, there was no absorption and so they could be used as standard substances in the measurement of dielectric constants. The results of measurements of the dielectric constant for glycerine, methyl, and ethyl alcohols, etc., are given at various temperatures and at given wave-lengths. Great variations in its value are found. Values ranging from that of the static field to the square of the refractive index for visible light are observed. The anomalous dispersion is accompanied by an intense absorption band. As the temperature is lowered the position of the anomalous dispersion shifts in the direction of the longer wave-length. According to Debye, the large values of the dielectric polarisation in a static field must be ascribed to the orientation of a molecule which has a permanent dipole in it. When a molecule rotates to adapt itself to external force, there must be a resistance which depends on the internal friction and the dimensions of the molecule. The experimental results are discussed from the point of view of this theory. The results obtained with alcohols are in good agreement with the dipole theory.

THE PHOTO BROMINATION OF *CYCLO*-HEXANE.—Pusch, and later Noddack, showed several years ago that in the photochemical bromination of *cyclo*-hexane vapour, each quantum of light absorbed effects the removal of one molecule of bromine. This result has been confirmed, and further data concerning the reaction have been published by B. J. Wood and E. K. Rideal in the October number of the *Journal of the Chemical Society*. Using the mercury green line, they found that the velocity of reaction varied directly with the light intensity, but was independent of temperature and of the concentration of *cyclo*-hexane. The presence of oxygen caused a reduction in the rate of reaction, and this was independent of the presence of *cyclo*-hexane. It is suggested that each quantum of absorbed radiation serves to excite one molecule of bromine, which then unites with a molecule of *cyclo*-hexane to form an excited complex $C_6H_{12}Br_2'$, which has a mean life of approximately 3×10^{-8} sec. This excited complex can either decompose spontaneously: $C_6H_{12}Br_2' \longrightarrow C_6H_{11}Br' + HBr$ and $C_6H_{11}Br' + Br_2 \longrightarrow C_6H_{10}Br_2 + HBr$; or it can, in the presence of oxygen, be deactivated by collision: $C_6H_{12}Br_2' + O_2 \longrightarrow C_6H_{12} + Br_2 + O_2 + \epsilon$.

THE SOLUBILITY OF WATER IN LIQUID CARBON DIOXIDE.—An attempt to determine the solubility of water in liquid carbon dioxide is described by H. H. Lowry and W. R. Erickson in the November issue of the *Journal of the American Chemical Society*. The method used was to determine the density of gaseous carbon dioxide coexisting with liquid, both in the presence and absence of water, since if the latter is soluble in liquid carbon dioxide, it should cause a decrease in the vapour pressure and, consequently, in the density of the co-existing gas. Known weights of carbon dioxide were sealed into glass tubes, calibrated for volume, and the volumes occupied by the gas and liquid measured. Assuming the critical temperature to be 31°, the critical density, obtained by extrapolation, was found to be 0·4683 in satisfactory agreement with previous values. Between $-5{\cdot}8°$ and $22{\cdot}9°$ the density of saturated carbon dioxide vapour is the same in the presence and absence of water, and the solubility of water in liquid carbon dioxide must therefore be less than 0·05 per cent. by weight over this range. At about 4° the formation of a hydrate was noticed; possibly this was $CO_2 . 9H_2O$ described by Hempel and Seidel (1898).

Annual Exhibition of the Physical and Optical Societies.

THE eighteenth Annual Exhibition of the Physical and Optical Societies took place on Jan. 10, 11, and 12 at the Imperial College of Science and Technology, London. The secretary, Mr. T. Martin, is to be congratulated on the excellence of the arrangements. When space is necessarily limited, as in this journal, in an account of an exhibition on so wide a scale only some typical features can be mentioned. The reader is referred for a detailed report to the *Journal of Scientific Instruments*, where the lectures will be published in full and a description of the principal exhibits given by experts on the various subjects. A new feature in the arrangements this year was that on the second day of the exhibition the morning was devoted to a private view by the members of the co-operating societies, of which full advantage was taken, and it is to be hoped that this will prove of increasing value. A larger number of visitors attended the exhibition this year, and there was also an increase in the number of firms (eighty-one) exhibiting apparatus, which covered a wide range, and in which the high standard associated with this exhibition was maintained.

Among the exhibits in the Trade Section the following may be mentioned: Messrs. Adam Hilger, Ltd., a travelling microscope measuring to one-tenth of a micron; a quartz spectrograph of the all-metal type; and a fluorite spectrograph. Messrs. Carl Zeiss (London), Ltd., an illuminated pointer on the principle of an advanced torchlight, as used in the planetarium at Jena; a microscope affording binocular vision with one objective only, the binocular tube being interchangeable with a monocular tube. Messrs. Charles Baker, a boxform dissecting microscope with sliding arm to carry arms and arm rests. The Automatic and Electric Furnaces, Ltd. a Wild Barfield high temperature furnace suitable for pottery work and high speed steel hardening. Messrs. Gallenkamp and Co., Ltd., a variety of apparatus, including electric furnaces for metallurgical and dental work, optical glass heat treatment, an optical table of new design. Messrs. W. Edwards and Co., a new method of absorbing mercury vapour from high vacuum systems by the use of liquid alloys of the alkaline metals, rendering the use of liquid air largely unnecessary. Messrs. Bellingham and Stanley, Ltd., a spectrograph specially designed to photograph spectra of feeble intensity; a simple spectrograph for industrial work, photographing eight spectra on a quarter plate; a simple form of arc lamp, burning a special metallic alloy, giving a spectrum about five times as intense as tungsten, in the region 2900 A. and 3100 A.; an ultra-violet lamp for use in the home, for radiating the body with actinic light; and the latest form of the Hartridge microspectroscope.

Among other exhibits, new devices shown by Messrs. Elliott Brothers (London), Ltd., were a portable moving coil galvanometer, combining high sensitivity with a robust form; vacuum thermocouples of various capacities, special feature being that the heater is insulated from the thermocouple itself. Messrs. Houghton-Butcher (Great Britain), Ltd., gave a number of demonstrations of educational films; a new lantern attachment was shown in which films or lantern slides can be projected alternately by one movement of a change-over switch. Among some interesting new developments seen in the exhibits of the Igranic Electric Co., Ltd., attention may be directed to the Igranic neutro-regenerative short wave amplifier kit, by means of which high frequency amplification on wave-lengths so low as 15 metres may be obtained. The Mullard Wireless Service Co., Ltd., demonstrated a loud speaker of very high quality, a combination of the horn and cone type with a balanced armature. To mention a few more, there were exhibits in connexion with recent developments in wireless apparatus (Marconi's Wireless Co., Ltd.); electrical aids for the deaf (Mr. W. H. Pettifor); temperature recording (Siemens Brothers and Co., Ltd.); thermometry (Messrs. Negretti and Zambra). Among the many interesting exhibits of the Cambridge Instrument Co., Ltd., may be mentioned an ingenious device used in their new recording potentiometer of the slide wire type, in which a balance is obtained automatically by the recorder mechanism instead of by hand manipulation of the slide wire contact.

In the Research and Experimental Section there were sixteen stands in the group of exhibits illustrating recent physical research. Among these exhibits, typical of progress in the development of physics in its application to various modern problems, were the following: The Rothamsted dynamometer, shown by Rothamsted Experimental Station, the chief characteristics of which are its light weight and adaptability for a widely different range of cultivation implements. The Technical Optics Department of the Imperial College of Science and Technology showed an equipment for ultra-violet microscopy for instructional purposes, and other apparatus and accessories in connexion with ultra-violet refractometry. The arrangements make possible theoretically a resolving power which is double that attainable with the green light of the visible spectrum, and permit of photographic application to biological or metallographic subjects.

Among the ingenious devices developed by the National Physical Laboratory for overcoming practical difficulties were an improved portable illumination photometer in which the lamp current can be adjusted to within a small fraction of a milliampere by means of a special bridge, and in this way the illumination can be kept very nearly constant; a modification of the Haughton-Hanson thermostat furnace, in which an oscillating temperature is produced by means of a clockwork device, while an upward or downward tendency can be imposed as desired on the temperature curve by another special device in connexion with the thermostat furnace.

In the section devoted to Lecture Experiments in Physics, Mr. C. W. Hansel's exhibit, which was of considerable interest to those concerned with teaching, consisted of a demonstration of the rapid construction of scientific apparatus from simple units, couplings, and accessories suitable for use in schools and colleges, and in connexion with this he gave an explanatory lecture each afternoon and evening. Dr. D. Owen's exhibit showed very effectively the appreciable time taken to establish a current in an inductive circuit. Mr. F. W. Shurlock had a set of diffraction slides, among which was a set illustrating the principal results of the wave theory of light.

In the Historical Section, Prof. E. N. Da C. Andrade had a series of illustrations of the early history of the air pump, while another series of pictures showed how closely the present types of rotary air pump were anticipated by early water pumps. The Research Department of Messrs. W. and T. Avery, Ltd., had an exceedingly interesting series of illustrations, specimens, and reproductions from the Avery Historical Museum, Soho Foundry, Birmingham, showing the development of weighing instruments. An important section of the exhibits of the Research Department of the Gramophone Co., Ltd., was a series of gramophones illustrating development from the earliest instruments to the present day. A striking feature in this section was a gramophone with an electric pick-up operating a coil-driven loud speaker, consisting of a light alloy sheet (stretched almost to its elastic limit) on a frame also of light metal. The coil is attached eccentrically to the sheet, thus preventing the formation of nodes and resulting in a purer tone than would otherwise be possible. This section was certainly the most audible in the Exhibition.

The lectures in the evenings again attracted large audiences. That on the first evening was given by Mr. Whitaker, of the Gramophone Co., Ltd., on "Progress in the Recording and Reproduction of Sound." The number of people interested in this subject was too large to be accommodated in the lecture theatre, and Mr. Whitaker therefore consented to repeat his address in order to avoid causing disappointment. He sketched the development of acoustic recording from the phonautograph of Scott and Koevig and the reproduction of sound from Edison's phonograph. Development up to 1925 was largely empirical, and the slow improvement in quality was demonstrated by a series of gramophones of different dates which played contemporary records. Improvement in the quality of response was traced from 1925 when electrical recording came into use, followed by electrical reproduction. An electrical reproducer was demonstrated that will give natural reproduction of tones as low as the pedal notes of an organ with very great volume. There are great possibilities in the method of recording and reproducing sound that utilises a photographic film, as moving parts are completely eliminated, except in the microphone and loud speaker. Photographs were shown demonstrating that reproducing devices which put a 'reactive' load on a record wear it excessively, proving that when special attention is given to this aspect a sound box which causes the minimum possible wear can be made, while an equally good pick-up scarcely wears a record at all.

Mr. V. E. A. Pullin, who lectured on the second evening, took for his subject "Recent Applications of X-rays." He gave an outline of the scope of the work of the Radiological Research Laboratory at Woolwich, illustrated by numerous slides typical of the matter with which he dealt. He sketched the origin of the work from a suggestion during the War that X-rays should be used to examine the bases of shells for flaws. This led to the planning of a scheme of research which involved the study and improvement of a wide range of technique. Among examples mentioned of practical applications were the study of gun steels, the effect of heat treatment and mechanical working, structure of electrically deposited metals, and a survey of many of the alloy systems. It has been found possible to develop X-ray technique so that comparatively large metal specimens can be radiographed, and to extend the use of X-rays beyond the research laboratory into the dockyards and factories of the services. Among the problems now receiving attention, the necessity of extremely high voltages for metal penetration is important. It is now possible to penetrate in a practical manner about 4½ in. of steel, whereas in 1917 the maximum penetration that could be achieved was 1 in.

On the third evening Dr. J. W. T. Walsh, of the National Physical Laboratory, lectured on "Artificial Daylight." He pointed out the importance of artificial daylight for certain types of work. The most exacting use, he said, is for colour matching, and this demands the closest of daylight with correspondingly lower efficiency. For general lighting purposes a higher efficiency may be obtained, and accuracy of imitation may be sacrificed to a considerable extent. The spectral distribution curves of a number of actual units were shown by Dr. Walsh, as well as the units themselves. Among them was the daylight gas mantle, in which a fair imitation of daylight can be obtained at an efficiency of about 80 per cent. of that of the ordinary mantle. Dr. Walsh urged that picture galleries should be illuminated by artificial daylight.

The Science Masters' Association.

THE Science Masters' Association has recently grown in numbers so rapidly that it was decided this year to hold the annual meeting on Jan. 4-6, partly in the Chemical Department of the Imperial College at South Kensington, and partly at King's College for Women, Campden Hill Road. The trade exhibition of scientific apparatus and books—the largest ever seen at these meetings—was displayed at the Imperial College throughout the meeting. The daytime programmes of lectures, meetings, and demonstrations were all at the Imperial College, but for those in the evening the large hall of King's College for Women was used.

The meeting was opened on the evening of Wednesday, Jan. 4, by the address of the president, Sir Richard Gregory, who took for his subject the relationship between science and the humanities. In the course of the address it was pointed out that these are the warp and woof of the fabric of modern life. Though in scientific assemblies this is commonly recognised, representatives of science miss reciprocity of attitude from their literary colleagues, who more easily find fault with the non-literary scientific worker than with the humanist wholly oblivious of science.

"It is commonly assumed," said the president, "that devotion to science inhibits all sense of pleasure in emotional expression and that familiarity with the structure and processes of Nature breeds indifference to her charms, and destroys the æsthetic veil which gives her both mystery and beauty. Science and poetry thus seem to most people to be poles apart, yet Coleridge said that he attended Sir Humphry Davy's lectures at the Royal Institution for the purpose of increasing his stock of metaphors, and modern poets might well be inspired by the scientific imagination of Sir William Bragg shown in his insight into the atomic structure of crystals. Though poetry and science represent different attitudes towards Nature, they are not mutually destructive, and may be complementary to each other.

"Science does not want a divorce from literature, but closer union with it and a common understanding of the distinctive qualities by which each can contribute to the fullness of life."

Sir Richard Gregory dealt also with the respective claims of classical and scientific education. "When a student of science confesses that he knows little or nothing of classical literature," he said, "he does so in a spirit of humility; but classical scholars often seem to be supercilious in their disregard of science. This vestige of social snobbery will no doubt disappear in the course of time, and it will be understood more clearly than it is to-day that science is as necessary a part of the mental equipment of a cultured man as is classical or modern literature or any other art of expression."

During the meeting two discussions were held on the subject of scientific careers. The first dealt especially with biological openings overseas. Sir John Farmer, who opened the discussion, made it very clear that in few directions are prospects so good for men of the right type and training, and that the present shortage of suitable candidates for work that is urgently needed is a very serious hindrance to the development in the Empire of what is by far its most important industry, namely, agriculture. Capt. Irby, of the Colonial Office, supplied details of recent appointments made in the Crown Colonies and Dependencies.

The second discussion dealt with industrial openings in chemical technology, and was opened by Prof. W. A. Bone. He pointed out that the formation of large industrial combines is tending to bring in more and more scientific research and control. The economic existence of Great Britain depends upon production, and production depends upon efficiency of control. For this the best type of men is needed, and of the qualifications required sound character is by far the more important, although adequate technical knowledge is also necessary. Prof. Bone thinks that proper training for work of this kind requires seven years after leaving school. Such a long and expensive course could be financed by industries themselves, who would find it a cheap and safe investment; some industries are moving in this direction already.

Lectures were delivered to the Association during the meeting by Dr. J. W. T. Walsh, of the Photometric Department, National Physical Laboratory, who lectured on "Some Modern Methods in Photometry"; also by Prof. J. C. Philip, of the Imperial College, on "Charcoal and its Activation." These lectures were well attended and much appreciated by audiences who, knowing well enough how easily a science master gets out of touch with modern developments, welcomed such chances of renewing contact with some recent investigations.

A large number of members exhibited apparatus designed by themselves for various uses in connexion with teaching. Among these, the most notable collections were those staged by Mr. E. H. Duckworth, of Dean Close School, Cheltenham, and Mr. F. A. Meier, of Rugby School. Lecture demonstrations were given by Mr. C. W. Hansel, Bedford School, in connexion with apparatus of his own design for use in mechanics and optics; by Mr. S. R. Humby, of Winchester, on experiments with high-frequency sound waves, in which he was able to demonstrate effectively most of the familiar phenomena of optics; and by Mr. W. A. D. Rudge, of Rugby School, who demonstrated atomic models. These exhibits and informal lectures by members were a very satisfactory feature of this meeting, in which they occupied a much larger part in the programme than has been the case at most recent meetings. One of the most useful functions of the Association is to enable its members to pick up valuable ideas from one another, and a distinct revival in this particular branch of its activities is therefore to be welcomed.

Among the most popular events at every annual meeting are the expeditions, applications for which commonly exceed the number that can be taken. On this occasion a tour of the London Docks was arranged during the afternoon of Jan. 4; visits to the United Dairies Ltd.; to the Lighting Service Bureau at 15 Savoy Street, Strand; and to the Æolian Hall, New Bond Street, to see the Duo-Art piano-playing reproduction process, filled the programme for the following afternoon. On Friday afternoon nearly 250 members accepted a generous invitation from the Gas Light and Coke Company. After they had been entertained to lunch by the Governor and Court of the Company, a very interesting afternoon was spent in viewing first the gas-producing plant at Fulham, where a large retort house of the latest type has recently been installed, and afterwards the Company's store and training depot at Nine Elms. The Governor, Sir David Milne-Watson, in welcoming his guests at lunch, expressed the view that some people were inclined to suppose that, with the competition of electricity, the gas industry would decline, and he hoped that they would be convinced of the contrary by what they would see during the afternoon. His hope was very fully justified.

It is hoped to meet next year, for the second time, at Cambridge, and Prof. A. C. Seward, Master of Downing College, has been elected president of the Association for the forthcoming year.

The Loutreuil Foundation of the Paris Academy of Sciences.

THE following grants for research have been made from the Loutreuil Foundation:

(a) Grants to institutions named by the founder.

(1) National Museum of Natural History. 4000 francs to Désiré Bois, to aid in the publication of the third part of a "Guide aux collections de plantes vivantes du Muséum"; 6000 francs to Paul Chabanaud, to pursue in Austria and Holland work relating to a general study, morphological and systematic, of the heterosome fishes. (2) Collège de France. 3000 francs to Charles Moureu for altering the large cathetometer in his laboratory with the view of the determination of the densities of gases, particularly of pure xenon and krypton. (3) Central Council of Observatories. 3000 francs to the Paris Observatory for the publication of Lalande's catalogue; 3000 francs to the *Journal des Observateurs* to assist this useful publication. (4) Conseil de perfectionnement de l'École polytechnique. 15,000 francs to the library of the École polytechnique, for the purpose of filling up the gaps in a certain number of periodicals. (5) National Veterinary School of Alfort. 11,000 francs to the library, to complete various collections and to purchase important French or foreign books relating to veterinary science. (6) National Veterinary School of Lyons. 5000 francs to the library for completion of collections of periodicals interrupted during the War; 1000 francs to Jean Basset, to carry on his researches against anthrax. (7) National Veterinary School of Toulouse. 3000 francs to Marcel Petit, for the study of the lymaphatics of the foot of the horse, especially those in the keratogen layer. (8) National Agronomic Institute. 2000 francs to Charles Voitellier, for experiments on egg control.

(b) Grants to institutions admitted for one year by the president.

Conservatoire national des Arts et Métiers. 5000 francs to Emilio Damour, for pursuing his bibliographical work on glass.

(c) Independent bequests.

3000 francs to Norbert Casteret, for continuing his researches and his spaeleological work in the region of the central Pyrenees. 6000 francs to the Comité français de géodésie et géophysique, towards the cost of the seventh survey of the new magnetic network of France, and the calculations necessary to the co-ordination of the observations collected. 5000 francs to Gaston Deléfine, for the pursuit of his studies on the carboniferous limestones of the Asturia. 5000 francs to the École supérieure d'aéronautique et de construction mécanique, for acquiring the necessary material for the determination of critical points and for experiments on hardness. 6000 francs to the École technique de photographie et de cinématographie, for completing the equipment of the research laboratories of the School in view of undertaking a systematic study of photographic preparations. 5000 francs to Gaston Fayet, to ensure the regular publication of the *Bulletin* of the Nice Observatory. 5000 francs to the Fédération française des Sociétés de sciences naturelles as a grant to the "Faune de France." 10,000 francs to the Musée d'histologie de l'hôpital Saint-Louis, for the purchase of instrumental material. 6000 francs to Emmanuel Passemord, to assist the continuation of his researches on the Quaternary period. 2000 francs to Paul Pallary, for assisting his zoological and prehistoric studies in Morocco. 10,000 francs to Pierre Teilhard de Chardin, to aid his geological and palæontological researches in northern China.

University and Educational Intelligence.

DURHAM.—Dr. A. K. Macbeth, reader in chemistry (Durham Division) since 1924, has been appointed to the Angas chair of chemistry in the University of Adelaide. In connexion with the changes following on Dr. Macbeth's departure, Dr. W. A. Waters has joined the staff of the chemical laboratories as a lecturer in chemistry.

EDINBURGH.—The Cameron Prize "awarded to a person who, in the course of the five years immediately preceding, has made any highly important and valuable addition to practical therapeutics," has been awarded to Prof. C. Levaditi, of the Pasteur Institute, Paris, for his work on the chemotherapy of syphilis and his other contributions to our knowledge of microbiology.

IT has been decided to found an institute at Prague for the scientific investigation of coal. It will have the support of the State and of the various coal undertakings in Czechoslovakia.

THE British Federation of University Women, Crosby Hall, Cheyne Walk, S.W.3, directs attention to the fact that applications for the first international junior fellowship offered by the International Federation of University Women and for the Rose Sidgwick memorial fellowship must reach the secretary by, at latest, Feb. 15.

THE annual general meeting of the Association of Women Science Teachers will be held at St. Paul's Girls' School on Feb. 4. In the morning, members of the Association will visit the Royal Institution; in the afternoon the programme will include short discussions on general science as an alternative to the separate sciences in the school certificate course (opened by Miss F. E. M. Morgan), and holiday work in chemistry for girls (opened by Miss C. H. Spencer). In the evening, Sir John Russell will deliver a lecture on "The Growth of Crops—Applications of Botany and Chemistry to Country Life." Further particulars can be obtained from Miss M. E. Birt, 20 Longton Avenue, Sydenham, S.E.26.

NOTICE is given that, subject to candidates of sufficient distinction presenting themselves, the president and Council of the Royal Society of London propose to appoint a second Foulerton research professor, whose duties will be to conduct original researches in medicine or the contributory sciences, calculated to fulfil the objects of the bequest, namely, "The discovery of disease, the causes of it, and the relief therefrom of human suffering." The yearly stipend will be not less than £1400 and the appointment will be made, in the first instance, for five years, renewable for further successive periods of five years up to the age of sixty years. Applications must be received by the assistant secretary of the Royal Society, Burlington House, W.1, not later than May 1.

THE Department of Textile Industries of the University of Leeds has been conducting researches in relation to the colloid character of wool, and these have led to the invention of a device, now being tried out on a large scale, for imposing some of the properties of wool on artificial fibres. Other main lines of research in the department, as reported in Prof. Barker's account of the work of the session 1926–27, related to the chlorination of wool and the physico-chemical properties of wool fat. The work on colour inheritance in animals associated with the institution of a White Wensleydale Flock is, for the time being, discontinued owing to lack of funds. Meanwhile the work already done has led to the Wensleydale-Peruvian Merino cross, with important results. In the Department of Colour Chemistry and Dyeing, satisfactory arrangements for obtaining free samples from manufacturers have made it possible to devote more attention to artificial silk.

THE education of the chemist forms a frequent theme of discussion, and very varied views are held concerning what he should and should not be taught. It has rarely been suggested that legal knowledge should form part of a chemist's equipment, but no one engaged in industrial work will deny that a working knowledge of the numerous Acts of Parliament, and the still more numerous Orders-in-Council and Statutory Regulations governing chemical works, is absolutely essential to anyone holding an appointment of an executive nature. The necessity of this knowledge has been realised by the Sir John Cass Technical Institute, which announces a short course of lectures on Tuesday evenings at 7 P.M. on "English Law as Related to Industrial Chemistry." As the lecturer, Mr. G. S. W. Marlow, is both a chemist and a barrister in practice, the requirements of the industrial chemist will be fully met. At the first lecture, which is to be given on Jan. 24, the chair will be taken by Mr. James Whitehead, K.C.

"ENGINEERING DEGREE SERIES" is the title of a new series of books being issued by Sir Isaac Pitman and Sons, Ltd., intended for students preparing for the national certificate, City and Guilds, associate memberships of the engineering institutions, and B.Sc. (Eng.) examinations. The publishers are to be congratulated on this series of primers, which are all clearly printed, well illustrated, and, what is probably most important, contain many well-chosen examples. The idea of publishing this series in weekly parts should make a wide appeal to part-time students who, although not in a position to purchase the necessary text-books outright, may welcome the opportunity of making weekly contributions towards this end. The scheme of covering the syllabus of the B.Sc. examination in eight to twelve weekly parts of about forty pages each seems rather ambitious, and students preparing for this examination will require to supplement their knowledge by reference to standard text-books. On the other hand, the subject matter of Parts I of "Strength of Materials," by Dr. F. V. Warnock, "Applied Thermodynamics," by Prof. W. Robinson, and "Performance and Design of D. C. Machines," by Dr. A. E. Clayton, seems to be clearly stated and condensed into as short a form as possible. This again will make a special appeal to the part-time student, who may receive at the most only thirty lectures in the subject during a session, and can, therefore, only hope to acquire the basic principles during class instruction. The series should thus meet a definite need, as one of the greatest difficulties of teachers in evening institutes is to recommend a text-book which will adequately cover the syllabus, and at the same time be within the limited purchasing power of the student.

Calendar of Customs and Festivals.

January 24.

St. Paul's Eve.—In Cornwall known as St. Paul's Pitcher Day or Eve of Paul's Tide, the former name derived from a curious custom of tin streamers, the mixed agricultural and mining population of Bodmin and the seafaring population of Padstow. The custom was that a pitcher should be set up at a convenient distance and pelted with stones until demolished. A new pitcher was then bought, with which an adjournment was made to the nearest ale-house, and the pitcher was used in the merry-making which followed. Popularly the custom was explained as a festival to celebrate the discovery of tin-smelting. A variant was observed in Bodmin when boys paraded the town with broken pitchers and threw sherds into any door which had been left open.

In Cornwall popular tradition has assigned super-human powers to its local saints freely. St. Just and St. Keverne hurl boulders at one another which elsewhere, and even in Cornwall, are the missiles of giants. Numerous wells were endowed by them with miraculous powers, such as that at St. Ludgvan, which protected any child baptised with its waters from being hanged. St. Kea floated to Cornwall from Ireland on a rock; and St. Piran was conveyed there on a millstone which had been hung around his neck when he was flung into the sea by the order of an ungrateful Irish king, whose hounds killed in hunting and whose warriors slain in battle he had restored to life. Previously he had fed ten Irish kings and their armies for ten days with three cows. The early connexion between Ireland and Cornwall is indicated by the Irish origin of a number of Cornish saints, and there was a similar link with Wales.

In view of the peculiarly localised character of Cornish saints, it might be expected that a distinctively local industry like tin mining, which goes back to a remote past, would be associated with a local saint rather than St. Paul; in fact, St. Piran and St. Chiwidden are credited with the discovery and working of tin. If the destruction of the pitcher represented a sacrifice, human or other, it might be simply a survival of a 'Celtic' rite; but the very fact that it is associated with an observance of tin-workers, and its restricted but peculiar distribution, which extends to the fishing as well as the mining population, suggests that the festival of St. Paul may have overshadowed a rite belonging to another culture, such as might be associated with the so-called "Cornish fisher type," found at Padstow among other places, which, distinct in physique and often in custom, still to some extent holds aloof from the rest of Cornwall.

January 25.

St. Paul's Day.—Strype records that on this day—the day of the conversion of St. Paul—a solemn procession, in which the civil dignitaries and representatives of all the parishes took part, was made through the City of London to St. Paul's. The court, on one occasion at least, was also present. At night bells were rung and bonfires were lit.

There are some curious features in an old custom connected with the tenure of lands in Essex from the Dean and Chapter of St. Paul's. The lands were held by the Le Baud family from 1274 on payment annually of a buck on the day of St. Paul's conversion and a doe on the Commemoration of St. Paul. The buck was brought to the steps of the altar, where it was received by the Dean and Chapter in full canonicals with garlands of roses on their heads. The head and horns of the buck were then placed on a pole and carried in front of the cross around the church until the procession came out of the west door, when the huntsman sounded the death of the buck and the city horns replied. Among the gifts to the huntsman from the Dean was a loaf bearing the image of St. Paul. This custom was discontinued in the reign of Elizabeth. There is no evidence to show whether the custom of carrying the horns in procession arose out of the terms of the tenure or whether, as is not improbable, the tenure was instituted to ensure the continuance of a custom which had grown out of a tradition connected with the previous use of the site for a pagan temple of great sanctity.

In popular belief St. Paul's Day is one of several days in the calendar connected with prognostication of the weather in the coming year. If the sun shines, it betokens a good year; if rain or snow, indifferent; if misty it predicts a great dearth; if it thunders, great winds and death. Another form of the belief holds that a cloudy day will be followed by pestilence. A number of forms of the prognostication are recorded. The belief is evidently of some antiquity and widespread. It is recorded by Hospinian. It is also recorded that in many parts of Germany, if it were cloudy on this day it was the custom to drag the images of St. Paul and St. Urban to the river—a familiar method of treating the images of saints popularly connected with the weather, but more usually to secure rain rather than avert it, as it seems in the present instances. In an ancient calendar of the church of Rome, this day is marked as one on which husbands do not lie with their wives.

St. Dwynwen's Day.—Formerly celebrated in Wales on Jan. 25 with many festivities, the trying of love spells, and the exchange of love tokens. The saint was the patron of lovers and of all between whom ties of affection prevailed. According to the legend, Dwynwen was loved by Prince Maelon Dafodrill, but a marriage had already been arranged for her by her father. Dwynwen prayed to be cured of her love, and dreamed that an angel administered a potion to her which effected her wish, but that a similar potion turned her lover to ice. The angel asked her to express three wishes. She wished her lover to be unfrozen, that all true lovers should either obtain the object of their affections or be cured of their love, and thirdly that they should never wish to be married. Her wishes were granted, and she then devoted herself to a religious life. Her symbol is the crescent moon, her girdle had the same attributes as the cestus of Venus, and she carried the bow of destiny, which on her last visit to earth she left at Tresillian Cave, Glamorgan, in the form of a natural arch of stone. This is used as a means of divination in connexion with marriage. If a pebble is thrown over the arch at the first attempt, it indicates a marriage within the current year. Each failure indicates a year to wait.

The similarity between the popular cults of St. Agnes and St. Dwynwen in connexion with marriage is apparent. The legend of St. Dwynwen, it may be conjectured, represents a working over and Christianising of a cult of a Celtic goddess, while in the case of St. Agnes the cult has been absorbed by the legend of a saint of which the central feature was a love episode. In both cases the desired end was not attained, and yet two virgin saints are associated with the forecast of a love affair with a successful issue, which clearly points to an imperfect assimilation of pagan-Christian elements. The Welsh legend attempts a logical solution by illogically granting the *faithful* lover forgetfulness.

Societies and Academies.

LONDON.

Linnean Society, Jan. 5.—**Suzanne Leclercq** and **M. Béllière**: *Psygmophyllum Gilkineti*, nov. sp., from the Middle Devonian (with Old Red Sandstone facies) of Malonne, Belgium. *P. Gilkineti* is an arborescent or at least suffrutescent plant. Axis woody, smooth, ramified, furnished with numerous distant, non-sheathing leaves, spirally arranged. Leaves large, coriaceous, and with long petioles. The whole extent of the principal specimen is about 1 ft. 10 in. in height by 3 ft. 2 in. in width, with leaves reaching to 18 in. in length, including the long and rigid petiole.—**S. H. Williams**: A naturalist in the Guiana jungles. Prof. Williams was in charge of the University of Pittsburg Investigations in British Guiana. The tropical research station, acquired from the New York Zoological Society, is situated at the junction of the Mazaruni and Cuyuni Rivers, in the heart of the largest and least-known jungle area in the world. Prof. Williams also travelled into the highlands in the interior, beyond Kaieteur Falls, in order to make a study of zonal distribution of Coleopterous insects.

GENEVA.

Society of Physics and Natural History, Dec. 1.—**G. Tiercy**: The variations of the radial velocities of η-Aquilæ, Y Ophiuchi and X Cygni. The author has proved a remarkable parallelism between the curve of radial velocities and the light curve of these three variable stars.—**P. Ferrero** and **R. Wunenburger**: Researches on the chlorination of naphthalene. The chlorination has been carried out in the gaseous state; the maximum yield of α-chlornaphthalene compared with the theoretical yield based on the naphthalene (60 per cent.) is realised at 350° C. with a ratio of 1·5 molecules of chlorine for one of naphthalene.—**A. Van der Wijk**: The formation of ammonia by the silent electric discharge in the presence of mercury. The author establishes that the velocity of the reaction varies according to the formula

$$V = -\left(\frac{\partial x}{\partial t}\right) = K[H_2][N_2]^{\frac{1}{2}},$$

which, for a maximum of V, requires a mixture of 67 per cent. hydrogen and 33 per cent. nitrogen.—**P. Balavoine**: A seasonal variation of the composition of butter fat. A diminution of the volatile acids is produced in August and September (23·5 against an average figure of 28) with a refractive index of 46 against 43·5 (measured with the Zeiss butyro-refractometer).—**R. Chodat** and **W. H. Schopfer**: Carotine and sexuality. The authors prove, by various reactions, that in the Mucorineæ the (+) progamete contains the carotine dissolved in a fat whilst this is not the case for the (−) progamete.—**E. Cherbuliez** and **P. Rosenberg**: Researches on the silicates. The increase of conductivity of orthose at constant temperature above 900° C. is explained by a dissociation, which leads to the final nepheline stage passing through the leucite stage. The variation mentioned exists for leucite but not for nepheline. This phenomenon does not take place with augite.

SYDNEY.

Royal Society of New South Wales, Dec. 7.—**H. B. Taylor**: The determination of minute quantities of metals in biological material (Part 1). The determination of lead. The lead present in urine is separated directly by adsorption on calcium oxalate formed by the addition to the urine of ammonium oxalate. The calcium oxalate precipitate is heated to convert it into carbonate, treated with hydrochloric acid, evaporated to dryness, taken up in water, made slightly alkaline, and filtered. The lead is left on the filter, together with a small amount of calcium phosphate. The lead is determined by dissolving the precipitate in hydrochloric acid, neutralising with sodium hydrate, and adding a freshly prepared solution of sodium-bisulphite. The amount of lead present is proportional to the opalescence produced. The method is capable of determining 0·005 mgm. of lead per litre of urine.—**A. R. Penfold**: The essential oil from the timber of rosewood (*Dysoxylon Fraseranum*). This excellent furniture timber suffers from the drawback of 'sweating,' due to the high content of oil and its peculiar nature. Although the wood is red in colour, the oil is viscous, with a pronounced bacon odour, and is intensely blue in colour, due to the presence of about 0·75 per cent. of azulene. The principal constituents were found to be cadinene, probably copaene, two new sesquiterpenes yielding azulene on dehydrogenation with sulphur, and a further sesquiterpene which has been named 'dysoxylonene.'—**Sir George H. Knibbs**: Proof of the laws of twin-births. Earlier analyses based upon means have shown that the ratios of the total number of twins born to mothers of any age, of cases of two males, of a male and a female, and of two females, were different functions of their age; the uniovular cases among them were always 0·00300 of the cases of maternity, whatever the age. Taking the masculinity into account, the numbers of uniovular and diovular cases for each year of age from 13 to 49, of *MM*, *MF*, and *FF* twins, agree very closely with the numbers actually observed in Australia in the six years 1920 to 1925. The formulæ were:

Ages.	Ratio.	Uniovular Cases.	Diovular Cases.
Up to age 37	$t =$	0·00300	$+0{\cdot}00058(x-15)$
Beyond age 37	$t =$	0·00300	$+0{\cdot}01276-0{\cdot}00128(x-37)$

The masculinity of the uniovular cases was 0·020, and of the *MM* and *FF* of the diovular cases, 0·040; t denotes the ratio of the cases of twins to the cases of maternity for mothers of age x.—**M. B. Welch**: Some mechanical properties of Australian grown *Pinus insignis* (*P. radiata*) with notes on the wood structure. The effect of rate of growth under different conditions has been studied in comparison with the mechanical properties of the wood. In general, slow growth results in a stronger wood. Impact tests indicate that the wood possesses remarkable toughness, especially material of fairly high density.—**W. R. Browne**: Petrological notes on some New South Wales basic alkaline rocks. Brief notes are given on a number of Tertiary basic alkaline rock-types, mostly from localities hitherto unrecorded; they comprise analcite and nepheline-bearing olivine-dolerites, a nepheline-basalt, and a teschenitic aplite containing barkevikite, recently collected from the Prospect intrusion.—**E. Cheel**: Descriptions of four new species of Boronia, with notes on certain other species. The new species described are: *B. subulifolia*, an 'awl-shaped leaved' species found on Mount Currockbilly near Braidwood which had previously been confused with *B. pilosa*, a Tasmanian species. *B. hispida*, a small plant covered with stiff hairs from the Grampian Mountains and head of the Turos River in N.S.W.; *B. Ruppii*, named after Rev. H. M. R. Rupp, who collected it near Barraba; and *B. Whitei*, which seems to be confined to the New England district, chiefly in the neighbourhood of Torrington. Five distinct species have previously been confused with the 'Ledum-leaved Boronia.' They are: *B. ledifolia* (Ledum-leaved Boronia); *B. rosmarinifolia* (Rosemary-leaved Boronia); *B. repandra* (Repand-leaved Boronia); *B. glabra* (Smooth-leaved Boronia); *B. triphylla* (Three-leaved Boronia), and *B. rubiginosa* (Rust-coloured Boronia).

Diary of Societies.

SATURDAY, January 21.

British Mycological Society (at University College), at 11 a.m.—Dr. E. J. Butler: Morphology of Catenaria in the Eggs of the Liver Fluke. —Miss M. M. Duke: The Genera Vermicularia and Colletotrichum.—N. C. Preston: A Cercospora Leaf Spot of Turnip.—J. Ramsbottom: Mycological Nomenclature.

Institution of Municipal and County Engineers (Southern District Meeting) (at Town Hall, Devizes), at 12 noon.

Institution of Municipal and County Engineers (Yorkshire District) (at Town Hall, Sheffield), at 2.—W. J. Hadfield: Report of the Royal Commission on Land Drainage.

Royal Institution of Great Britain, at 3.—Prof. R. W. Chambers: Some Tudor Biographers (I).

Physiological Society (in Department of Physiology, King's College), at 4.—Prof. J. Mellanby: The Preparation and Properties of Secretin.—

D. T. Barry: Cardio-inhibitor Threshold of Vagus in Relation to Perfusion Pressure.—H. Dunlop: The Duration of the Action of Pituitary Extract on the Circulation.—Prof. R. J. S. McDowall: The Production of High Blood Pressure by Small Doses of Histamine.—Prof. J. Barcroft: Effect of Pregnancy on the Size of the Spleen.—Demonstrations:—(a) The Recording of the Velocity of the Pulse Wave in Animals, (b) The Automatically Developing Camera, (c) A Simple Fluid Circulator, (d) A Convenient Anæsthetic Spray, by Prof. R. J. S. McDowall and R. A. Collier.—The Effect of the Circulation on the Electrical Resistance of the Skin, by H. E. A. R. Denham and H. M. Wills.—Specimens Illustrating the Comparative Physiology of the Epiglottis, by V. E. Negus.—The Estimation of Chlorides in Biological Fluids, by R. K. Christy and W. Robson.—Chromosome Linkage in Œnothera, by Prof. R. Ruggles Gates.—The Effect of Temperature Gradients on the Early Development of the Frog and Chick, by M. A. Tazelaar and M. E. Shaw.—Stromuhr, by H. Barcroft.—Section of Externised Intestine, by Prof. J. Barcroft.

HULL ASSOCIATION OF ENGINEERS (at Technical College, Hull), at 7.15.—L. C. Perkin: Gyroscopic Aids to Navigation.

MONDAY, JANUARY 23.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Influence Exerted by the Thyroid and Parathyroid Glands on the Growth of the Body.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section, London), at 6.30.—C. G. Bainbridge: Cutting Steel and Iron with Oxygen.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—E. W. Dorey and C. S. Buyers: Discussion on Power Factor Correction.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—A. H. Law and J. P. Chittenden: Higher Steam Pressures and their Application to the Steam Turbine.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—W. Ellard-Styles: Large Electric Baking Ovens.

INSTITUTION OF WELDING ENGINEERS (at Caxton Hall, Westminster), at 7.30.—A. E. Plumstead: Electric Welding Repairs to Inflated Gasholders.

ROYAL SOCIETY OF ARTS, at 8.—Dr. A. E. Dunstan: The Scientific Foundation of the Refining of Petroleum (Cantor Lectures) (2).

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—A. Bulleid: On Apical Infection.—H. P. Baylis: Case of Necrosis of the Mandible.—W. Rushton: An Abnormally Small Premolar.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.30.—President's Address and Presentation of Prizes.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Capt. C. J. Morris: Some Valleys and Glaciers of Hunza.

TUESDAY, JANUARY 24.

ROYAL DUBLIN SOCIETY (in Science Room, Ball's Bridge, Dublin), at 4.15.—Dr. J. H. J. Poole: Atomic Mechanics.

INSTITUTE OF CHEMISTRY (Bristol Section) (jointly with Bristol University Chemical Society), at 5.—Prof. A. Smithells: What has become of Inorganic Chemistry?

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—P. R. Coursey: The Development of Dielectrics for Electrical Condensers (2).

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Leeds University), at 7.—Dr. S. Z. de Ferranti: Electricity in the Service of Man (Faraday Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (jointly with Institution of Post Office Electrical Engineers) (at Milton Hall, Manchester), at 7.—H. C. Gunton: Recent Applications of Power in the Post Office.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group), at 7.—Capt. G. I. Finch: Mountaineering Photography.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—Exhibition of Opaque Objects under Various Methods of Illumination.

ROYAL ANTHROPOLOGICAL INSTITUTE (Anniversary Meeting), at 8.30.—H. J. E. Peake: Presidential Address.

ILLUMINATING ENGINEERING SOCIETY.—Discussion on Various Problems in Illuminating Engineering.

WEDNESDAY, JANUARY 25.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.30.—Dr. G. Carter: Tests for Drunkenness, particularly in Relation to Motor Accidents.

ROYAL SOCIETY OF MEDICINE (Tropical Diseases, Dermatology, and Comparative Medicine Sections), at 5.—Special Discussion on Cutaneous Mycoses in the Tropics. Opener: J. Ramsbottom (for the Section of Tropical Diseases).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Present Position of Knowledge Regarding the Manner in which Sex Glands Exert their Influence on the Growth of the Body as a Whole and on its Special Parts and Organs.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. J. K. Charlesworth: The Glacial Retreat from Central and Southern Ireland.

GLASGOW UNIVERSITY ALCHEMISTS' CLUB (at Glasgow), at 7.30.—Prof. A. Findlay: The Appeal of Science.

SOCIETY OF DYERS AND COLOURISTS (Midlands Section) (jointly with Foreman Dyers' Guild) (at Globe Hotel, Leicester), at 7.45.—G. H. Ellis: Dyeing Hosiery containing Celanese.

ROYAL SOCIETY OF ARTS, at 8.—H. de Koningh: Enamels.

EUGENICS SOCIETY (at Linnean Society), at 8.—R. B. Kerr, Dr. F. C. S. Schiller, and others: Super-men and Sub-men.

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Medical Society of London, 11 Chandos Street, W.), at 8.30.—Dr. D. N. Hardcastle: A Physiological Approach to the Problem of the Unconscious.

THURSDAY, JANUARY 26.

ROYAL SOCIETY, at 4.30.—Prof. F. Horton, Dr. A. C. Davies, and U. Andrewes: Critical Potentials for Soft X-Ray Excitation.—H. Gough: The Behaviour of a Single Crystal of α-Iron Subjected Alternating Torsional Stresses.—R. W. James, I. Waller, and D. Hartree: An Investigation into the Existence of Zero Point Ener in the Rock Salt Lattice by an X-Ray Diffraction Method.—*To read by title only*:—Dr. H. T. Flint and J. W. Fisher: The Fundamental Equation of Wave Mechanics and the Metrics of Space. B. Swirles: The Internal Conversion of γ-Rays.—A. Muller: On th Input Limit of an X-Ray Tube with a Circular Focus.—J. E. Science Teaching in England.[1]

THE inclusion of the history of science in the curriculum of higher educational institutions, although very belated, is on many grounds warmly to be welcomed, and there appears to be no reason why its complement, the history of science teaching, should not also be given a place, particularly in the time-table of the future science teacher. At first sight it seems somewhat strange to speak of the history of science teaching, unless we use the word 'science' in a very wide sense; for the teaching of positive, experimental science is of such recent growth that it can scarcely claim to have a history; but what it lacks in age it makes up in importance, at least as a sidelight on the development of the scientific spirit. This is evidently the view of Miss Turner, who, in a volume recently published upon science teaching in England, has devoted only about one-half of her text to the history of teaching proper; her aim has been "to indicate in outline the growth of the scientific spirit in England, and the relationship of that growth to the development of a system of education into which the teaching of science gradually became incorporated." For this reason she transports us back in time to Thomas Aquinas, Roger Bacon, and Descartes, whose eminence as philosophical thinkers and writers was in no way matched by their achievements as scientific investigators, and who in the light of modern developments can scarcely be regarded as science teachers.

Apart from the writing of books and treatises, it may be said that systematic teaching of experimental science did not exist until the latter half of the nineteenth century. Teaching before that time was confined to a few private individuals, whose names have mostly been forgotten, and to such pioneering bodies as the Royal Society and the Royal Institution, the results of whose labours must at the time have been very small. The first educational movement that struck at the esoteric character of science was the founding of Mechanics' Institutes early in the nineteenth century, and this was supplemented later by the formation of local literary and scientific institutions for the express purpose of popularising literature and science.

In reading Miss Turner's interesting sketch of the dawn of science teaching in England, one cannot fail to be impressed by the extraordinary retarding power of tradition, especially in the ancient and pious foundations of Oxford and Cambridge and in the great public schools. Although isolated attempts were made to teach experimental science in Oxford so early as the year 1704, it was not, we are told, until the second half of the nineteenth century that science secured a recognised place in the universities and a standard of academic teaching became established. Those early giants, Dalton, Young, Robert Brown, Darwin, Joule, Davy, and Faraday, received no training in experimental methods; and even the great mathematical physicists, Green, Stokes, Clerk Maxwell, and Kelvin, had no chance to do experimental work while they were at Cambridge. The backwardness of university science teaching in those days must not be charged to the investigators themselves, but to those in authority, whose policy seems to have been based upon the Platonic injunction of pursuing astronomy with the help of problems, like geometry, and of letting the heavenly bodies alone. On the whole, it must be confessed that Oxford and Cambridge played a very minor, if not an inglorious, part in the dissemination of natural knowledge; that task was left to the Mechanics' Institutes, local scientific societies, private individuals, and later on to the Royal College of Chemistry and the School of Mines. Under the lead of Huxley the last-named did really effective work in bringing science within reach of the masses.

---

[1] History of Science Teaching in England. By D. M. Turner. Pp. x+208. (London: Chapman and Hall, Ltd., 1927.) 7s. 6d. net.

The course of events in the schools was very similar to that in the ancient universities, the dead hand of tradition inhibiting any tendency to advance. The grammar schools and their derivatives, the nine great public schools, turned a deaf ear to the claims of science until well on in the nineteenth century, and it was only near its close that systematic instruction in science became at all general. Later developments are within the experience of most living teachers, but the recording of them was well worth while, if only as a guide for future workers. Some disappointment will, however, be felt that no attempt is made to use the past for illuminating the present by reference to the difficulties and disabilities of present-day science-teaching, and to indicate solvents for removing some of the blots that still disfigure the educational escutcheon. Miss Turner's story, illustrating as it does that inertia to the very idea of change is among the most characteristic qualities of the academic mind, nevertheless shows clearly that the thoughts of men do widen, and that therefore we should attempt to discern the lines along which future advance will proceed, so that we may try to facilitate its progress. Much excellent work is being done in our secondary schools; there is also some that is unworthy of the name either of science or of education; and there is a large intermediate class of teaching which is ineffective for one or more reasons; it may be too academic; it may be crippled and despiritualised by fear of the examination bogy; and what is still more important, the general organisation of the school may handicap or stultify the best efforts of the most gifted teachers.

Although lip-service may be done to science in the prospectus and at the annual prize-giving, the classical tradition still holds undisputed sway in too many of our schools, where the classical side is recruited mainly from the most promising pupils, whose success in after-life is claimed as convincing proof of the superiority of gerund-grinding and the study of grammatical forms. What hope is there of progress? History answers that we must look to the man rather than to the machine. In the past, reforms have been effected by men like Huxley, Clerk Maxwell, and Sanderson of Oundle, who combined high ability with outstanding fearlessness of character. It is to schools like Sanderson's Oundle, which do not fear to break with tradition and yet retain those character-forming elements that constitute the pride and justification of our great public schools, that we must look to supply the innovators and catalysers that our educational system still requires.

Primitive Marriage and Kinship.

(1) *The Mothers: a Study of the Origins of Sentiments and Institutions.* By Robert Briffault. In 3 volumes. Vol. 1. Pp. xix+781. Vol. 2. Pp. xx+789. Vol. 3. Pp. xv+841. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Co., 1927.) Each vol. 25*s*. net.

(2) *The Mystic Rose: a Study of Primitive Marriage and of Primitive Thought in its Bearing on Marriage.* By Ernest Crawley. A new edition, revised and greatly enlarged by Theodore Besterman. In 2 volumes. Vol. 1. Pp. xx+375. Vol. 2. Pp. vii+340. (London: Methuen and Co., Ltd., 1927.) 30*s*. net.

STUDENTS of primitive mankind still indulge too frequently in bitter and futile controversy; their reputation on this score is deservedly bad, and anthropology, I fear, could well be described as the study of rude man by rude people. Among the various hotly discussed subjects, perhaps the most contentious is primitive sexual life and mating—the much disputed 'marriage of the missing link.'

The appearance of two remarkable books on this subject, each standing for one side of the vast controversy, is a notable event, and affords a good opportunity for a statement of the problem as it now stands. One of the books, Crawley's "Mystic Rose," well brought up-to-date by Mr. Besterman, is exactly twenty-five years old, yet it is not only entirely fresh, but also in many respects it is bound to lead modern research for yet another quarter of a century. The other book, Mr. Briffault's "The Mothers"—in size and erudition an imposing achievement—leads us back to the early 'seventies, to the speculations of Bachofen, Morgan, and MacLennan. It is, in fact, an attempt to revive their now antiquated point of view that mother-right combined with sexual communism was the original form of organisation. Between them these two books represent a long span of anthropological history; the new contribution its past and the old one its future; while both mirror the present deadlock.

The anthropology of to-day can be divided into two camps on the issue of primitive marriage and kinship: those who believe in original monogamy and those who uphold the hypothesis of promiscuity. Was primitive man sexually promiscuous, or was he monogamous? Was he a thoroughgoing communist in wives and chattels, or a possessive individualist? Was he complaisant or jealous? Was it patriarchy or mother-right which shaped early institutions? Range Andrew Lang, Westermarck, Crawley, Lowie, and Kroeber on one side, and Frazer, Hartland, Rivers, Müller-Lyer on the other, and the latter will vote for communism, group-marriage, mother-right, and complaisance in the 'missing link' or primitive man, and the former for his monogamy, jealousy, and private possession.

(1) In my opinion, the problem has been distorted by this black-and-white, yea-or-nay treatment, and I regard it as the main defect in Mr. Briffault's book that he fights on the side of communism, as well as of mother-right, without compromise or reservation. The main thesis of the book is that mother-right was the source of social organisation, that male influence was entirely irrelevant in the dawn of culture, and that kinship, political organisation, the beginnings of law, economic life, magic, and religion were created and completely dominated by woman. To establish this, Mr. Briffault maintains that the maternal instinct is the sole origin of all tender emotions, hence also of all human organisation. Sexual love, on the other hand, leads to cruelty rather than to affection, and has been socially and culturally barren. "The mothers are the basis and the bond of the primitive social group. . . . The male takes no share in the rearing of the young. . . . Fatherhood does not exist."

It is difficult, perhaps, to reconcile this conception of the mother as a source of all affection and all social cohesion with the use which Mr. Briffault makes of her when he tries to explain the origins of exogamy by brutal expulsion of the males. In this context he describes her as: "a fierce enough wild animal . . . uncontrolled and violent . . . an object of horror . . . to the young male, terror-stricken by the anger of a despotic mother." The book is full of such provoking and fantastic exaggerations.

Mr. Briffault leaves no place whatever for the male in early culture. Such extremely important institutions as age grades, secret societies, initiation ceremonies and male political organisations are completely ignored in this work. Again, the rôle of the mother's brother in mother-right is scarcely accounted for; yet a male who intrudes into the very heart of maternal institutions is a formidable difficulty for the champion of an exclusively female culture. Avunculate, one of the most important features of matrilineal societies, is scarcely touched upon by the author—the word is not in the index.

The author then proceeds to prove that group marriage and sex communism exist, and in the course of this discussion commits himself to such extraordinary statements as that "among animals the maternal and derivative, parental, filial, and fraternal instincts operate in accordance with the 'classificatory,' and not with the 'descriptive' system of relationship. It would appear that it is the former that is in a biological sense 'natural,' and the latter which is 'artificial.'" The classificatory system in fact seems so 'natural' to Mr. Briffault that he does not discuss it at all, nor does he, in the whole three volumes, give any analysis of primitive kinship, a gap really astounding in a work dealing with mother-right—which is after all but one aspect of primitive kinship.

In the following chapters Mr. Briffault informs us that "girls and women who are not married are under no restrictions as to their sexual relations. . . . To that rule there does not exist any known exception." Since we know that, according to Mr. Briffault, married women also indulge in 'group-marriage', and other forms of 'licence,' continence and individual sexual relations seem to have been completely absent from primitive life. As a matter of fact, the statement quoted is a most misleading generalisation, inaccurate in wording, unsupported by evidence, and based upon a fundamental misconception of human marriage and sexuality. After an account, given from his point of view, of primitive sex communism, group-marriage, sexual selection, and the various manners of concluding marriage, Mr. Briffault proceeds to attribute to woman the discovery of totemism, witchcraft and religion.

It would be easy to indict "The Mothers" for its dogmatic and one-sided affirmations; for the straining of evidence, sometimes to the breaking point; for unsatisfactory definitions—or absence thereof—in such capital concepts as marriage, communism, kinship, avunculate, and mother-right. Much space is wasted in futile controversy; above all in virulent attacks upon Prof. Westermarck, generally by first distorting his views and then destroying them. On the other hand, the contributions of Crawley and Sidney Hartland, and the new and important work of Schmidt and Koppers, are completely ignored. Briffault's three enormous volumes might almost be called an 'encyclopædia of matrimonial errors.' The work, however, will be useful to a student, even though he reject most of its conclusions; for it gives a clear, well-written, and certainly unreserved statement of one side of the main problem of anthropology. To the amateur it will prove attractive reading as an introduction; and will be the more useful for its dramatic, strong, and effective narrative, which rivets the attention more forcefully and leaves a sharper imprint upon the memory than a well-balanced, hence less colourful, account might do.

As a contribution to science the work has one or two real merits. It is the most exhaustive though one-sided account of the influence of maternity upon the cultural rôle of woman. In the discussion of that subject the author clearly sees and, to the best of his ability, discusses the relation of innate endowment to social institutions in the shaping of human nature; and, in my opinion, anthropology will in the future have to be more concerned with the place of culture within biological development and with the relation of instinct to institution, than with questions of 'origin,' 'evolution,' 'history,' or 'diffusion.'

(2) The biological foundations of culture, which Mr. Briffault attempts to consider in his new work, have already been fully discussed in the "Mystic Rose," where the psychology of human relations is explained by what Crawley has termed *physiological thought*. The book sets out to discuss the many strange customs and institutions which centre round sexual life—the couvade, sexual taboos, various avoidances, and ceremonies of marriage.

Crawley resolutely rejects all explanations in terms of survival from such original conditions of mankind as 'sexual communism,' 'mother-right,' and the total eclipse of the male sex. He regards these as imaginary fantasies constructed against all evidence. He also maintains that the "indiscriminate and careless use of the terms *survival* and *rudiments*" is one of the main sources of anthropological error. On both points anthropology will, in my opinion, have to follow his lead and become inspired by his methods.

The explanation of savage custom and institutions must be given in terms of primitive thought. When Crawley, in his brilliant analysis of savage mentality, declares that "primitive thinking does not distinguish between the natural and the supernatural, between subjective and objective reality," his wording is not quite satisfactory; yet even in this slight misrepresentation of what he terms "primitive logic," Crawley, in forestalling the theories of Lévy-Bruhl, Danzel, Vierkandt, and their followers, must be regarded as the pioneer of modern developments of the problem of primitive psychology. He himself, however, has eschewed the extravagances of some of his successors. He does not commit the fallacy of assuming that the savage has a mind different from that of civilised man. ". . . Human nature remains fundamentally primitive. . . . Primitive ideas . . . spring eternally from permanent functional causes. . . . Ordinary universal human ideas, chiefly connected with functional needs, produce the same results in all ages; and many so-called survivals, which have on the face of them too much vitality to be mere fossil remains, at once receive a scientific explanation which is more than antiquarian." These statements strike the keynote of the soundest developments in modern anthropology. In laying down this point of view, and in carrying it through consistently, Crawley has laid the foundations for the scientific treatment of primitive sexual and social relations.

The main form which "physiological thought" takes in the primitive mind, that is, in the human mind as we find it universally, is a strong apprehension of danger arising from contact with other human beings, especially when there is an element of the abnormal or unusual in the relation. Strangers, people in critical condition—such as sickness, death, or functional crisis—and, above all, people of the other sex, are surrounded with an aura of supernatural fear. In savage culture such dangers are met by two devices: the taboo, and the ritual breaking of it.

Taboo is considered by Crawley as an inevitable by-product of human psychology; and, in a masterly survey of primitive social relations, we are shown how the various imperatives and prohibitions arise naturally out of savage life and savage outlook. Crawley constructs no hypotheses, invokes no *deus ex machina*—he explains quaint features and unrelated details in terms of intelligible and fundamental fact; he introduces order, he links up apparently disconnected phenomena and transforms the strange and unknown welter of "primitive superstition" into a familiar and comprehensible scheme of essentially human behaviour.

The taboo between men and women in its various aspects is treated against the background of mixed attraction and fear, of distrust undermining love—an attitude which is shown to dominate the relations between the two sexes. In this Crawley has anticipated the various theories of primitive society based on the principle of sex antagonism, theories set forth by Heape and several other writers long after the first edition of the "Mystic Rose" was published. In Crawley's work we also become acquainted for the first time with that emotional complexity underlying all social relations, especially as between men and women, which has been systematically worked out by A. F. Shand in his theory of sentiment ("The Foundations of Character"). Under the title of 'ambivalence' we have had similar phenomena dished up in a somewhat distorted shape in psycho-analytic literature. Crawley, in fact, can be described as the sane and sober forerunner of psycho-analysis, which, when the "Mystic Rose" was written, was unknown beyond a narrow circle of Viennese practitioners. It must also be remembered that psycho-analysis did not turn its attention to problems of primitive culture until a decade after the present book was first published. The "Mystic Rose," in the due emphasis which it places on sex, in its clear and courageous, but never fantastic or overheated, interest in that impulse, can be placed side by side with Havelock Ellis's "Psychology of Sex" as a pioneer in modern, scientific treatment of human love and mating.

In his theory of ritual and sacrament as mechanisms of breaking the taboo; in his theory of union; in his description of change and exchange; and in his analysis of the ritual in vital crises, Crawley has been a forerunner of several now developed branches of anthropology. To him can be attributed the first statement of the theory of *rites de passage*, afterwards so successfully developed by Schurtz, van Gennep, and Hutton Webster. He was the first to regard the sacrilisation of crises of life as the main function of religion—a theory to which he returned in his later work ("The Tree of Life"). His doctrines of change and exchange, of reciprocity and the principle of contact, are akin to the views of the French sociological school, especially of Durkheim, Hubert, Mauss, and Davy.

Finally, in the last part, a penetrating and original analysis is given of primitive kinship and relationship: that pivot problem and eternal puzzle of the anthropologist. In my opinion it ranks side by side with the first few chapters of Westermarck's "History of Human Marriage" as the best treatment of kinship yet given. Had such writers as the late Dr. Rivers, Mr. Briffault, and other latter-day Morganians read, digested, and assimilated the last three chapters of the "Mystic Rose," we would have had better field-work and fewer speculations about 'anomalous marriages,' 'group-motherhood,' and 'savage communism.' Even on this last point, Crawley, though not especially interested in economics, had a sound and a realistic view. All anthropological evidence, he maintains, tends "to disprove the common idea that early society had a communistic and socialistic character. The 'rights' of the individual in property, marriage, and everything else were never more clearly defined than by primitive man." Recently we have been told by a great authority that the Melanesians are 'communistic.' That such a view is based on superficial observation, and that Crawley is right here, as almost everywhere else, I have attempted to prove ("Crime and Custom in Savage Society").

The foundations of Crawley's work are so sound, so firmly established in the bedrock of human nature rightly understood, and of human culture correctly interpreted, that anthropologists will have to build on them for generations to come. To show this, one aspect of his views might be further developed in this place. Crawley has taken the primitive conception of the danger in sexual selection as the fundamental and irreducible datum. He speaks of "that difference of sex and of sexual characters which renders mutual sympathy and understanding more or less difficult"; and he adds: "woman is one of the last things to be understood by man." Again: ". . . woman is different from man, and this difference has had the same religious results as have attended other things which man does not understand." He also speaks of "the instinctive separation of the sexes hardening into tradition and finally made the subject of taboo."

Now I think that here it is possible for modern anthropology to go a step further and to interpret the psychological attitude of primitive man by its cultural function. I maintain that sex is regarded as dangerous by the savage, that it is tabooed and ritualised, surrounded by moral and legal norms—not because of any superstition of primitive man, or emotional view of or instinct about strangeness, but for the simple reason that *sex really is dangerous*.

The sexual impulse has to be experimental if it is to be selective; and it has to be selective if it is to lead to the mating of best with best. This is the eugenic principle which I believe governs human marriage as well as animal mating. Hence sexual jealousy and competition is to be found in human societies, and it harbours serious disruptive forces for any social group living in close contact. In animal societies, rut not only allows the law of battle and sexual selection to operate in especially favourable circumstances, but it also circumscribes the duration of the disruptive impulse and thus eliminates most of its dangers. In man rut is absent, and sex holds him in permanent readiness and tension. Cultural regulations, the various taboos and barriers step in and fetter him, where natural endowment has left him freer than the beast. They safeguard the family by the prohibition of incest, the clan by rules of exogamy, and the bonds of marriage by the ban on adultery and what might be called the principle of legitimacy. This argument cannot be fully developed or substantiated by evidence in this place; nor is it necessary for me to do so, since my views are developed at some length elsewhere ("Sex and Repression in Savage Society").

In human culture, however, no physical force is sufficient without moral support; no social regulations, however strongly backed by executive power, can be effective without mental assent. The social and cultural rules which separate primitive man and woman in daily existence, at initiation, during the crises of life, in economic occupations, and within certain social groups, cannot stand without the support of some system of thought and belief. Here, indeed, we find all those ideas which express the danger of sex—the ideas of evil and sin—at the very core of love and passion; the conviction that highest happiness in erotic union can only be obtained at the cost of infinite pains and precautions; belief, in short, that sex is religiously sacred, *sacer*, that is, at the same time holy and polluting. The universally human conception of sex must be explained, I think, by its function within culture rather than by mere reference to primitive psychology and the early conditions of life. The sexual taboo, then, and the ideas upon which it rests, appear to us indispensable corollaries of culture and of the influence of this on the increased plasticity of instinct which, since in man it has become more free, more experimental, and therefore more dangerous than in the animal, needs elaborate regulation. The barriers imposed upon sex by culture—that is, the taboos and the correlated primitive conception of sex dangers—appear to us as an inevitable by-product of the change wrought in human endowment by the passage from the state of Nature to that of culture.

I hasten to add that this functional view is implied at many points in Crawley's argument, though it is nowhere clearly formulated by him. It is really implicit in his own concept of the primitive *Weltanschauung*, in which beliefs and ideas do not exist as useless 'idle survivals,' not as 'speculations of rude philosophers,' or even as 'mistaken associations of ideas.' Crawley treats these simple and often quaint 'savage superstitions' as what they really are: life forces, indispensable moral values which shape the destinies of mankind with a determinism as binding though not as rigid as that which obtains in the physical world. Thus Crawley has given us in the "Mystic Rose," what is, perhaps, the first truly scientific work of comparative anthropology, and he must be regarded as one of the founders of what is now known as the functional method of modern anthropology.

B. MALINOWSKI.

Electrical Research and Development.

The Interaction of Pure Scientific Research and Electrical Engineering Practice: a Course of Advanced Lectures delivered before the University of London, October and November 1926. By Dr. J. A. Fleming. Pp. x + 235. (London: Constable and Co., Ltd., 1927.) 15*s*. net.

THIS book by Dr. Fleming is a delightful record of the research, discovery, and development which has lain behind the infusion of electricity into the life of civilised lands over the last fifty years. It is written with the intimate knowledge and enthusiasm of one who has himself been a worker and a keen contemporary observer throughout the period, and whose name will always be associated with some of its pioneer achievements. But perhaps of even more importance, Dr. Fleming has been unrivalled in the way in which he has interpreted the results of research to electrical engineers, applying always the latest discovery to the practical everyday technical problems, and expressing results in engineering units and magnitudes. He always sees the romance in every new theory or discovery, and seeks to make others see it too.

The book under review is characteristic. To those who know Dr. Fleming, more cannot be said. The reader is taken rapidly from one subject to another. Insulation, magnetism, thermionics, telephony, arcs, sparks, and glow discharges, radio, surges and pressure rises, electro-chemistry, and many other matters, are passed in review. The main historical features of each are traced, but the author hastens always to the latest development of each subject and leaves with the reader a vignette picture of the art as we know it to-day.

Dealing as he does with so many phases of electrical engineering, Dr. Fleming is careful not to assume on the part of the reader expert knowledge in any. His object is clearly to interest each branch of the profession in the advances of the others, and to show how almost every development has been the result of scientific research; research, not always with a deliberate objective in view, but always with a keen look-out for the unexpected and the anomalous.

Such a book would be easy to criticise. Where names and origins are mentioned freely, where there are a few pages only for handling each large subject, there must be important omissions and often lack of balance. The part in advances played by Great Britain is certainly not minimised. Electrical machinery and plant is scarcely touched upon, although its evolution has resulted from the same research and investigatory activity as in other branches. Nor is there in the book any effort to analyse the mass of examples with the view of drawing conclusions as to how research can best be encouraged or directed. One can quite believe that the attempt would be baffling. The spirit of research bloweth where it listeth; and it is the man of imagination and observation who produces results. Such have been found in all walks of life—in the factory as well as in the university—and it would be very difficult to deduce, from the evidence before us, rules for securing results. The few generalisations which Dr. Fleming allows himself are to be found in the concluding pages and are worth special note, for they are the mature conclusions of one who has worked long and hard and has a right to judge. Perhaps we may quote a few sentences:

> "Many of the problems which invite inquiry lie on the borderland of two or three sciences. These are best dealt with by carefully organised team work in which specially trained workers in the respective sciences have a share and co-operate and, in any case, call for a scientific education not framed on too specialist lines." And again: "Genius cannot be produced at will. . . . Let us see to it, then, that whenever found, it shall be given adequate opportunity for labours which, even if they seem entirely destitute of practical value at the moment, will certainly yield the fruit at some future time in divers and very unexpected ways."

This book should please all who peruse it. If a reader should feel that he already knows well any part in which he is expert, there will be much with which he is less familiar that will fascinate and instruct.

Our Bookshelf.

New Year's Day: the Story of the Calendar. By S. H. Hooke. (The Beginning of Things Series.) Pp. vi + 89. (London: Gerald Howe, Ltd., 1927.) 2*s.* 6*d.* net.

The Golden Age: the Story of Human Nature. By H. J. Massingham. (The Beginning of Things Series.) Pp. vii + 88. (London: Gerald Howe, Ltd., 1927.) 2*s.* 6*d.* net.

Corn from Egypt: the Beginning of Agriculture. By Dr. Maurice Gompertz. (The Beginning of Things Series.) Pp. vii + 88. (London: Gerald Howe, Ltd., 1927.) 2*s.* 6*d.* net.

THESE three little books form part of an interesting series of popularisation dealing with the early history of civilisation. Mr. Hooke in "New Year's Day" traces the history of the calendar and describes the principal calendrical systems which are or have been in use at different periods and in different parts of the world. Mr. Massingham's "Golden Age" is a book of a more philosophical type. It is a statement of the position in regard to primitive culture with which Mr. Perry has made us familiar, namely, that early man was a pacifist who has degenerated under the influence of advancing civilisation. It seeks to demonstrate that the views of classical writers on the Golden and succeeding ages were substantially correct. Mr. Massingham justifies his theory in the case of palæolithic man by an appeal to the 'faultless artistry' of the drawings in the French and Spanish caves—a psychological argument which the history of art would perhaps not bear out.

In "Corn from Egypt," Dr. Gompertz describes the development of agriculture. His attractively written and well-reasoned sketch is an exposition of the view that agriculture originated in Egypt.

While the evidence is still too uncertain to admit of any conclusion approaching finality, there are certain considerations in favour of a Mesopotamian origin to which Dr. Gompertz might have given fuller weight, and certain facts which he should have taken into account, such as the wheat discovered by the Weld-Blundell Expedition at Kish. Further, although Mesopotamian dating is not final, agricultural implements from Abu Shahrein may turn out to be as early as any from predynastic Egypt, while the undoubted occurrence of wild wheat and barley in Syria has to be weighed against the inferential attribution of the latter to Abyssinia. The evidence is given in summary in Mr. Harold Peake's presidential address last year to the Royal Anthropological Institute. The argument from the Isis-Osiris cult is no more in favour of an indigenous Egyptian origin than the Ea legend, which the author rejects as in favour of Mesopotamia. Osiris was not Egyptian in origin, but came from the north, while the Isis legend is connected with Byblos.

Memoirs of the Geological Survey of England and Wales. The Geology of the Southern Part of the South Staffordshire Coalfield (South of the Bentley Faults). By Talbot H. Whitehead and T. Eastwood. With contributions by Dr. T. Robertson. Pp. xi + 218 + 13 plates. (London: His Majesty's Stationery Office; Southampton: Ordnance Survey Office, 1927.) 6*s*. 6*d*. net.

WHEN Jukes wrote his classic memoir on the South Staffordshire Coalfield, the Thick Coal was being actively mined. To-day it is almost completely worked out, except in the concealed fields beyond the boundary faults, and the surface geology of much of the coalfield is that of tip-heaps and slag-mounds; nevertheless, the authors of the present memoir, under the scrupulous editorial guidance of Mr. T. C. Cantrill, have compiled a concise, yet detailed, account of the Productive Coal Measures, showing their variations, structures, and probable limits on the south and west. The marshalling of the scattered and often obscure data relating to these measures is very skilfully done. Numerous plates of vertical sections supplement the descriptions.

In view of the importance of a proper understanding of the cover overlying the Productive Series, now that any new coal-ventures must needs take place below them, there is a full treatment of the Upper Coal Measures, in which the authors include not only the Etruria, Halesowen, and Keele Groups, but also provisionally the Enville Beds and even the Clent and Warley Breccias. The Hopwas Breccia is, however, regarded as more closely related to the Trias. These conclusions are reached after a critical review of the data and of the interpretations advanced by other observers.

The re-survey has shown that contemporary movement directly related to pre-existing structural axes was going on during the deposition of the Productive, Etruria, and Halesowen Groups, so that the thicknesses vary considerably from place to place. The detailed mapping appears to have disproved Kay's contention that there is an unconformity below the Etruria Marls; and, on the other hand, it seems to have demonstrated that the Halesowen Group is locally unconformable.

The structure of the sub-Carboniferous floor and of the coalfield itself is fully discussed, and the repetition of movement along some of the structural lines is emphasised. A chapter is devoted to the underground extensions of the coalfield and another to the associated igneous rocks.

An innovation in the index may be noted with approval. The names of authors quoted in the text are printed in capitals, and in this way a separate bibliography is avoided. The whole book is a very careful piece of work that fully maintains the standard set by Jukes. L. J. W.

(1) *Vorlesungen über theoretische Mikrobiologie.* Von Prof. Dr. August Rippel. Pp. viii + 171. (Berlin: Julius Springer, 1927.) 6·90 gold marks.

(2) *The Principles of Practical Bacteriology: for Scientific Workers.* By J. H. Johnston and Dr. R. H. Simpson. Pp. viii + 110. (London: J. and A. Churchill, 1927.) 5*s*.

(3) *An Introduction to Laboratory Technique in Bacteriology.* By Prof. Max Levine. Pp. xii + 149. (New York: The Macmillan Co., 1927.) 5*s*. 6*d*. net.

(1) THIS excellent little book by the professor of agricultural bacteriology at the University of Göttingen is designed chiefly for the use of non-medical students requiring instruction in general bacteriology and particularly in the chemistry of bacterial growth. Of the thirty-four brief lecture-chapters in the book, more than a dozen are devoted to the study of bacterial enzymes and bacterial metabolism generally. Considerable knowledge of organic chemistry is essential for the full appreciation by the student of this portion of the work. The volume closes with a brief sketch of immunity problems and an etymological glossary of biological terms.

(2) It is often desirable that technical workers in fields not primarily bacteriological should have some elementary knowledge of the general characters of bacteria and the principles governing their investigation. It is to meet this demand that Messrs. Johnston and Simpson's small volume has been written. The basic principles of the subject are dealt with in a very simple way, and no attempt is made to give instruction in technique or to acquaint the reader with the different members of the bacterial species.

(3) Prof. Levine's book is based upon a laboratory course in elementary bacteriology at the Iowa State College, U.S.A. It is arranged in the form of a series of exercises covering the commoner phases of the subject. A list of materials required for each exercise is given, together with instructions, and a number of questions at the end designed to test the student's knowledge of what he has just performed. The scope of the book is limited to elementary general bacteriology, and does not extend to special branches of the subject.

Penrose's Annual: the Process Year Book and Review of the Graphic Arts. Edited by Wm. Gamble. Vol. 30. Pp. xvi + 160 + 68 + 59 plates. (London: Percy Lund, Humphries and Co., Ltd., 1928.) 8*s.* net.

THE business of Penrose and Co., with which this *Annual* has been associated from its commencement, has been acquired by the firm of Hunters, Ltd., and will henceforth be known as Hunter-Penrose, Ltd. Mr. Wm. Gamble retires from the business, but will continue to edit the *Annual*, so doubtless its character will be fully maintained. The present volume is on the same lines as those that have preceded it.

The editor in his introductory remarks pleads for a more kindly attitude toward the inventor, for a greater receptiveness of new ideas, and for a bolder enterprise. He finds little that is new to record, but a general if slow progress along the lines that have been indicated in previous years. Perhaps the most striking item is the use of chromium plating for printing surfaces. Chromium is harder than steel, indeed a hardened steel graver will not cut its surface, and it can scarcely be scratched by any form of mechanical abrasion. After 240,000 impressions had been taken, there was no visible deterioration in the prints or in the plate. Another plate was still in use after a run of five million printings.

Mr. Chas. T. Jacobi gives the seventh of his series of descriptions of private presses—The Golden Cockerel Press, which was projected in 1920, and issued its first volume in the following year. Specimens are given. Mr. Paulson Townsend contributes a well-illustrated article on the history of woodcuts and wood engraving. Mr. S. H. Horgan deals with the beginnings of half-tone, and gives a reproduction in facsimile of the first published example in the *New York Daily Graphic* of Mar. 4, 1880. There are many other articles, and a large number of illustrations that show the high standard of present-day process work.

The Principles of Pathology. By Dr. Charles Powell White. (Publications of the University of Manchester: Medical Series, No. 17.) Pp. x + 279. (Manchester: At the University Press; London: Longmans, Green and Co., Ltd., 1927.) 15*s.* net.

PATHOLOGY is a subject to which considerably more attention is paid in the medical curriculum than was the case fifteen years ago. The student, however, still tends to regard it as static rather than dynamic, and this error is not sufficiently corrected in books and in the post-mortem room. Dr. Powel White's "Principles of Pathology" is not a text-book devoted to the description of macroscopic and microscopic appearances; the subject is approached from the biological aspect, and causes and processes are considered rather than nature and appearances. A comparatively small volume, it must be somewhat dogmatic in style, and though this is no disadvantage to the student, it renders the author's views more open to criticism. The term 'diathesis,' which is now rarely used in clinical medicine, is employed to group a number of conditions ranging from hæmophilia to neurasthenia and the tendency to bed-sore formation in paralysed patients. Psycho-pathology is so unsettled that the application of this term to abnormal mental states simply obscures them further; and it seems scarcely advisable to include bed-sore formation, which is as readily explicable as is the severance of the skin by a knife.

Dr. Powell White, however, does not dogmatise in the attitude of a final authority. He writes rather to attract attention and to stimulate thought, and in this his book should be successful. It will certainly assist the student to regard pathology, not as the product of laboratory and microscope, but as a biological science.

The Infancy of Medicine: an Enquiry into the Influence of Folk-Lore upon the Evolution of Scientific Medicine. By Dr. Dan M'Kenzie. Pp. xiv + 421. (London: Macmillan and Co., Ltd., 1927.) 15*s.* net.

THIS work, which emanates from a prominent London otologist with whom the study of folk-lore plays the part of the violin of Ingres, constitutes an attempt to show in what manner and to what extent primitive thought has influenced the evolution of the science and art of medicine. The work, as we learn from the preface, is intended not only for the small section of the medical public interested in medical history, but also for all practitioners of medicine, in that it seeks to explain the more obscure workings of the partially educated lay mind in civilised communities as well as in the savage and semi-civilised races of the world.

The book is divided into two parts. The first consists of three chapters, devoted respectively to the evolution of the medical man, primitive pathology, and primitive treatment; while the second part, which forms the bulk of the work, contains fourteen chapters dealing with the evolution of animal and botanical remedies, astrology in medicine, the evolution of balneology, primitive surgery, and midwifery, various superstitions and practices connected with menstruation, impregnation, and pregnancy, circumcision and other mutilations. An extensive bibliography for each chapter is appended. The work, which shows a characteristic blend of scholarship and humour, will appeal alike to the medical man and the anthropologist.

General Chemistry: Theoretical and Descriptive. By Prof. Thomas P. M'Cutcheon and Prof. Harry Seltz. Pp. x + 415. (London: Chapman and Hall, Ltd., 1927.) 16*s.* net.

"THIS book has been designed for use in a course of General Chemistry based on a series of illustrated lectures and quiz hours, and for a text of reference for the student performing the laboratory work, which usually accompanies such a course." It has probably been of value for this purpose, but it cannot be commended for independent reading, and it is unlikely that it will find any extensive field of usefulness where 'quiz hours' are not the normal method of 'cramming.'

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Hydrogen Molecule.

RECENT experimental and theoretical work by Richardson, Witmer, Dieke and Hopfield, Hori, Burrau, Condon, Dennison, Sugiura, and others, makes possible a reasonably certain determination of the more important constants of the hydrogen molecule and molecule ion. In order to compare the results of different investigators, it is essential that these be calculated consistently according to some adopted interpretation, and with definite values of the basic constants. I should like especially to emphasise the necessity of distinguishing results in terms of the new wave mechanics from those in terms of the older quantum mechanics. Failure to make such a distinction has already led to a number of errors in the published literature.

In a paper which will appear shortly in the *Proc. Nat. Acad. Sci.*, I have given the more important details concerning such a recalculation and intercomparison of the available data for hydrogen. The purpose of the present communication is to examine critically the results and to consider certain additional facts and conclusions. *All* data and constants are given here in terms of the *old* mechanics. Transformation equations for the two systems are given in the paper just mentioned.

Richardson (*Proc. Roy. Soc.*, A, **115**, 528; 1927) has definitely identified the final (lower) state of his '*A*' and '*B*' bands with the initial '*B*' state of the *A*-*B* ultra-violet bands of Dieke and Hopfield. With an assumed Rydberg formula for the upper levels of these two systems, one obtains 15·34 volts for the ionisation potential of the neutral molecule. This should be accurate to about 0·01 volt. Richardson believes that this value cannot be reconciled with the electrical determination of about 16 volts, but Condon has shown that such an apparent discrepancy is to be expected, and the chief object of the present work is to show that this lower value is entirely satisfactory.

If I_M and I'_M represent the ionisation potentials of the neutral and ionised hydrogen molecule respectively, D the normal heat of dissociation, and I the ionisation potential of the atom, then $I_M + I'_M = D + 2I_A$. Of these four quantities only I_A (= 13·54 volts) is accurately known. For the other three quantities we have the following data. The best value of D is 4·34 ± 0·1 volts from Witmer's extrapolation of the vibrational levels of the normal state. (Dieke and Hopfield's determination of 4·38 volts is based on a probable misinterpretation of the spectrograms, according to later unpublished work by Hopfield.) The best value of I'_M is 16·16 ± 0·03 volts, as calculated by Burrau (*Danske V. S. Math.-fys.*, **7**, No. 14; 1927). His result of 1·402 R (= 16·30 volts) is in terms of the *new* mechanics. Dr. E. U. Condon has directed my attention to the fact that, due to an error in one of Burrau's formulæ, the correcting factor (s^+) should be 0·14 volt, and not 0·07 volt as calculated by Burrau.

With $I_M = 15{\cdot}34$ volts, there is just 0·08 volt discrepancy between the three suggested values. I believe it most probable that I_M and I'_M are correct, as given, and that $D = 4{\cdot}42$ volts. The value of $I_M = 15{\cdot}34$ volts can be checked also by means of the heats of dissociation in the various excited states of the molecule. In the case of every level for which data are available, the agreement, as shown in my longer paper, is remarkably good.

The recent work of Hori gives $0{\cdot}48 \times 10^{-40}$ as a very trustworthy value of I_0, the moment of inertia of H_2 in the normal state, and this checks with Dennison's value from the specific heat curve. For the '*B*' level only B_1 is reliably known, but with a reasonable assumption as to the value of α ($B_n = B_0 - \alpha n$), I obtain B_0 and finally $I_0 = 1{\cdot}99 \times 10^{-40}$. This is just twice the value given by Richardson, but is the value to be expected in view of the very small magnitude of ω_0 for this level. The process by which Richardson calculates I_0 from known vibrational data, plus the value of α, but *without* knowing B_0, is most interesting. It is based on Kratzer's expression for the potential function of a *polar* molecule and gives for I_0 a value 5 per cent. too low, as applied to HCl.

So far as I know, Richardson's method has never been tested on a non-polar molecule. I have accordingly carried out such a test for several non-polar molecules for which trustworthy data are available and find that this method gives values of I_0 ranging from 8 per cent. too large for the excited level of the Swan bands to 9 per cent. too small for the excited level of the CN violet bands. Assuming Hori's values of I_0 for the normal and the '*C*' level of H_2, the same method gives results 21 per cent. and 26 per cent. too large respectively. Using my own probable value of α (0·614) for the *B* level, the Richardson method is correct to within 3 per cent. His value of $\alpha = 2{\cdot}22$ is derived from extremely uncertain data and cannot be correct, since even with his own doubled value of B_0 (27·8), it indicates that the mean moment of inertia becomes infinite for only 12·5 quanta of vibrational energy. The vibrational data, on the other hand, show that at least 42 quanta are needed. Richardson's other values of I_0 are probably roughly correct, and the product $I_0\omega_0$ shows the expected rough constancy for *all* levels, including the *B* level, *if* $I_0 = 1{\cdot}99$ is used.

By extrapolating to ionisation the values of ω_0 in a given Rydberg series, one obtains an estimate of ω_0 for the normal state of H_2^+. My own result for this is 2247 cm.$^{-1}$, which corresponds to $s^+ = 0{\cdot}141$ volt, in remarkable agreement with Burrau's value (*as corrected*), calculated directly on the new mechanics. The heat of dissociation of H_2^+ is given by $(D + I_A - I_M)$, and with the values finally adopted equals 2·62 volts. Burrau calculates I_0 for H_2^+ as $0{\cdot}927 \times 10^{-40}$, and the fact that more than *double* this value is found in the *B* level of H_2 is most astonishing, and has interesting consequences.

RAYMOND T. BIRGE.

Spatial Distribution of Photoelectrons Produced by X-rays.

JUDGING from recent papers on this subject, there seems to be considerable diversity of opinion concerning the explanation of the *dispersion* or 'spread' of the photoelectrons, whilst there appears to be no disagreement about the cause of the *longitudinal asymmetry*, which is generally assumed to correspond to the transfer to the photoelectrons of the momentum of the absorbed radiation. J. M. Nuttall, H. S. Barlow, and the present writer (hereinafter referred to as N.B.W.) recently investigated the longitudinal distribution of photoelectrons, and the results (not yet published) indicate an average forward component of momentum of the photoelectrons which is appreciably greater than the momentum, $h\nu/c$, of an incident quantum. The writer has also made a closer quantitative study of the results of other observers, and finds that with the exception of P. Auger's results an 'excess asymmetry' is revealed in each case. As regards dispersion, experimental results seem to prohibit all theories except one, with which there is fair agreement.

According to E. C. Watson (*Proc. Nat. Acad.*, 584, Aug. 1927) the dispersion observed by the Wilson cloud method is entirely due to nuclear scattering of the photoelectrons within the volume represented by the photograph of the first droplet in a Wilson track. The magnitude of this effect depends directly on the diameter of the first droplet, and calculations similar to Watson's show that in the photographs examined by N.B.W. the dispersion due to nuclear scattering in the first droplet is very small compared with the observed dispersion, which is of the same magnitude as that observed by others. We must conclude that the observed dispersion undoubtedly exists when the electrons leave their parent atoms. Attempts have also been made to explain the dispersion by secondary processes *within* the parent atom, such as scattering by the 'parent' nucleus or the effect of the momentum of the electrons in the atoms before absorption. The dispersion afforded by such theories is, however, wholly inadequate, especially in the case of light elements (cf. A. H. Compton, "X-rays and Electrons," p. 247), and the rapid decrease of dispersion with decreasing atomic number which they require receives no corroboration at all from experiment. There remains the "$\cos^2\theta$" law first enunciated by Auger and Perrin and since derived by Wentzel on the wave mechanics. According to this law (provided we overlook longitudinal asymmetry) the probability of emission in a direction making an angle θ with the electric force in the incident wave is proportional to $\cos^2\theta$, and is independent of the atomic number of the atom and the wave-length of the rays. The dispersion is attributed entirely to the dispersion of the 'photo-electric impulses' and no secondary process within the atom is involved. This law represents satisfactorily the lateral distribution observed by Kirchner using polarised rays and the longitudinal dispersion observed by Auger and N.B.W., the experiments involving considerable variation of atomic number and wave-length. Bubb and Loughridge find somewhat less dispersion than is required by the $\cos^2\theta$ law. These, however, are the only discrepancies, and we may say that the $\cos^2\theta$ law leads to distribution functions which are, on the whole, the best representations of the experimental results for dispersion that can be chosen.

Air . . .	0·37-1·0	1000	1·5	—	—	C. T. R. Wilson (1923)
Air . . .	0·71	250	2·1	—	—	O. K. Defoe (1924)
O_2, Argon .	0·71	450	2·1	2·3	2·0	D. H. Loughridge (1927)
Argon . .	0·13	300	1·4	1·3†	—	F. Kirchner (1927)
N_2, O_2 . .	0·54-0·71	1000	1·4	1·4	1·4	N. B. W. (1927)

The quantities usually considered in measuring the longitudinal asymmetry are the ratio, ρ, of the forward to the backward emission, and the bipartition angle, ϕ_H. The average forward component of momentum, μ, of a photoelectron is also a significant measure of the asymmetry, but up to the present it has not been considered. In order to correlate the asymmetries represented by different quantities, and thereby compare the results of different observers, it is convenient to regard the longitudinal distribution as the result of adding to each vector in a distribution of momentum vectors obeying the $\cos^2\theta$ law, momentum of magnitude $\sigma.(5/4).(h\nu/c)$ in the forward direction, the magnitude of the initial momenta being such that the resultant momenta are consistent with Einstein's equation. The factor 5/4 is introduced in order that $\sigma=1$ may correspond to an average forward momentum of the photoelectrons equal to $h\nu/c$. σ can be regarded as a coefficient of asymmetry and its values, which correspond to the results of N.B.W., and other observers are given in the accompanying table. Except in the case of Defoe's results, the values of ρ, ϕ_H, or $\overline{\cos\phi}$ as the case may be, have been deduced from other published data. [It is interesting to note that according to the theory of Perrin and Auger, in which σ is taken equal to 4/5, the average forward momentum of a photoelectron is $(4/5).(h\nu/c)$.]

The last row in the table gives the results obtained by Nuttall, Barlow, and the writer. These observers made direct observations on the average value of $\cos\phi$ where ϕ is the angle with the forward direction, and the results indicate a forward momentum of the photoelectrons equal to about 1·4 times the momentum of the absorbed radiation. A. H. Compton ("X-rays and Electrons," 251) considers that the "electrons are ejected with an average forward momentum equal within experimental error to the momentum of an incident quantum." This is, however, not in agreement with the above result. Attention should be directed to the agreement in the last row between the values of σ deduced from different quantities, because it justifies, so far as it goes, the scheme adopted in building up the longitudinal distribution.

It is seen from the table that the results of other observers also lead to an 'excess' asymmetry, though the variation in the value of σ is not very satisfying. The experimental results of P. Auger are not included in the table. These lead to a value of σ differing inappreciably from unity and they require special mention for that reason. The differences between the results of various observers is not easy to explain. They may be due to the choosing of tracks or the use of non-homogeneous X-rays. What is desired to emphasise here is that it must not be assumed that *existing* experimental results show that the momentum of the photoelectrons is equal to that of the absorbed radiation. The results rather indicate that the photoelectrons have forward momentum nearly 50 per cent. greater than this.

As possible reasons for the excess asymmetry may be suggested (1) the effect of the nucleus or (2) the effect of the other k electron, both of which have up to the present been neglected. In individual quantum absorptions the nucleus must absorb momentum of magnitude comparable with that of the photoelectron, in order to conserve momentum, and this seems to the writer to invalidate the assumption that the nucleus can be neglected on account of its massiveness. The possibility of the other k electron being involved is suggested by the recent work of Prof. Alexander on the absorption of X-rays (*Phil. Mag.*, Oct. 1927).

E. J. WILLIAMS.

6 North Terrace,
Cambridge.

---

* Denoting $\sqrt{h\nu/mc^2}$ by a, then $\cos\phi_H=(5/4)\sigma a$, $\overline{\cos\phi}=\sigma a$, and $(\rho-1)/(\rho+1)=(15/8)\sigma a+(15/8)\sigma a/8$ approximately.

† Kirchner gives the distribution of the tracks on the photographic plate and 'works back' to the space distribution, finding $\phi_H=73°$ which gives $\sigma=0·8$. It seems to the writer that ϕ_H must be close to 60°, giving $\sigma=1·3$ which agrees with σ_ρ.

Differential Response of Barley Varieties to Manuring.

IT is a well-known fact that, by selection or hybridisation, varieties of any one plant can be produced which differ markedly in their yielding capacity. It is generally undecided as to what this difference of yielding capacity is due, and although yielding capacity of plants is controllable by manuring, it is not known whether the increase in yield gained in this way is a function only of the manure added, or whether different varieties respond to varying extents to the manurial combinations given. Interesting results were obtained in an investigation which has been carried out to test the efficiency in the use of manures by five well-known varieties of barley. Eleven manurial combinations consisting of different amounts of phosphate, nitrogen, and potash were used. The experiments were done in pot culture, using pure sand and solutions of pure chemicals. Each manurial combination was replicated seven times, giving in all 385 pots. The manurial scheme is tabulated below. The varieties used were Goldthorpe, Plumage, English Archer, Plumage Archer, and Spratt Archer.

TABLE I.

SCALE OF MANURING EMPLOYED (GM. PER POT).

	Phosphate-deficient Manuring.			Complete Manuring.	Nitrogen-deficient Manuring.			Complete Manuring.	Potash-deficient Manuring.		
	A.	B.	C.	D.	E.	F.	G.	H.	I.	J.	K.
P_2O_5 .	0	0·02	0·10	0·50	0·50	0·50	0·50	0·50	0·50	0·50	0·50
N . .	1·50	1·50	1·50	1·50	0	0·06	0·30	1·50	1·50	1·50	1·50
K_2O .	1·00	1·00	1·00	1·00	1·00	1·00	1·00	1·00	0	0·04	0·20

Varietal differences in response were apparent in all the types of manuring. The difficulty of separating variations in yield due to experimental error from differences in yield due to manurial treatment, varietal differences in general, and differential varietal response to the various manures, was met by application of R. A. Fisher's 'Analysis of Variance.' By this means it has been possible to separate out the various effects, and to estimate their significance.

The effect of immediate interest here is the differential varietal response with the different manures. This is shown in the table below where the varieties are compared in pairs.

+ indicates a significant positive difference.
− indicates a significant negative difference.
0 indicates no significant difference.

The absence of significant differences in Series I and J is almost certainly due to the great variability in these two sets.

A yield significantly greater in favour of the first variety is shown by a +, while a − indicates that the second variety has produced a significantly greater yield; zero indicates no significant difference in yield. It will be seen that for any one pair of varieties the relative magnitude of yield differs in an orderly way with the manuring; thus where a significant increase of the first variety over the second was obtained in the phosphate-deficient combinations, the order is reversed in the potash-deficient sets, and so on. Furthermore, even where no significant differences are found with complete manures, such differences show themselves in the partially deficient sets.

The facts presented in Table II. establish a difference in efficiency in the use of manures by these varieties, and further show that for different varieties tested over the same range of manurial combinations, it is not always the same manurial constituent which in minimum has the most marked effect on relative yield.

The agricultural bearings of the results obtained are twofold: (1) Varietal trials must be combined with manurial trials to be complete, and (2) the lines along which to develop selection and breeding of varieties to meet the requirements of different soil types are indicated.

The Nebulium Spectrum in New Stars.

IN a recent communication (NATURE, Jan. 7, p. 12) O. T. Elvey has applied the 'expanding shell' theory of novæ to calculate the maximum density at which oxygen can be made to give the nebulium spectrum. In Nova Aquilæ, No. 3 (discovered June 8, 1918), the line λ5007 was first seen on June 27, when its breadth was 55 A.; and the gases are therefore assumed to have been travelling outwards for 19 days with a velocity of 1700 km./sec. before reaching a low enough density to emit this line. If, then, the phenomena are due to the reversing layer of the star being blown off bodily as a shell of gas, we can find the density in the shell at any moment after the outburst, given the initial density and radius. Elvey finds in this way that at the first appearance of the nebulium lines the gas must have a density of the order 10^{-17} gm./c.c.

There is a serious objection to the foregoing reasoning, however, which becomes apparent if we consider the state of ionisation of the gases concerned. The lines λλ5007, 4958, and 4363 are due, according to Bowen, to the O^{++} atom, which has an ionisation potential of about 35 volts. We can, therefore, find at once from the Russell-Saha formula the various pressures and temperatures at which O^{++} atoms will just begin to appear (say 0·1 per cent.); and it follows that at the density given, the lowest admissible temperature is

$$T = 13{,}000° \text{ Abs.},$$

corresponding to a partial electron pressure $p_e = 2 \times 10^{-13}$ atm. (This is about half the total pressure.) Now if we apply Elvey's method to hydrogen, which on June 27 showed bright bands of identical width with that of the nebular ones, it is evident that the hydrogen too must have had a density of the order of 10^{-17} gm./c.c. on that date. The condition that it shall not all be ionised (say

99·9 per cent. only) imposes an upper limit to the temperature; we must have

$$T < 6000° \text{ Abs.}$$

Now it is obvious that at these densities the ionisation is mainly due to the radiation from the star; and so the relevant temperature must be the same for both shells of gas. This, of course, is incompatible with the foregoing conditions.

As time goes on, the density continues to fall, and the discrepancy becomes worse. After three months, hydrogen and nebulium bands are still present together, their widths remaining sensibly constant, though the hydrogen is now relatively much weaker. Thus it appears that the straightforward argument put forward by Elvey yields results which are self-contradictory; and careful consideration is necessary before his figures can be accepted.

Another way of looking at the matter is as follows: The lowest temperature at which two substances with different ionisation potentials I_1, I_2 can coexist at the same partial electron pressure is $T = 840\ (I_2 - I_1)$, where 'coexistence' means that not more than 99·9 per cent. of the one substance is ionised, nor less than 0·1 per cent. of the other. For a mixture of hydrogen and 'nebulium' this gives $T = 18,000°$ Abs., corresponding to a minimum pressure $p_e = 2 \times 10^{-8}$ atm. and a density 4×10^{-7} gm./c.c.

If we suppose that these values apply three months after the outbreak, then, working backwards, the critical density at which the nebular lines first appear must be of the order 10^{-5} gm./c.c. at a pressure of about an atmosphere.

This is, of course, directly opposed to the idea that metastable transitions can only occur at very low pressures; but it is conceivable that very high temperatures might also be capable of inducing them. The strength of the ultra-violet continuous spectrum is a well-known feature both of novæ at a certain stage, and of O-type stars, which can also stimulate the nebulium spectrum.

A more probable way out of the difficulty, however, is to suppose that the oxygen and hydrogen shells originate in different layers of the star. There will be hydrogen accompanying the oxygen, of course, and no doubt helping to produce the complicated dark line spectra which appear in the early days; but by the time the nebular stage is reached, this hydrogen will be completely ionised. The hydrogen that is actually seen then must have come from deep down in the star, where the density was much higher than in the reversing layer.

This explanation unfortunately undermines Elvey's argument, for once we admit that the shells of gas come from different regions of the star, we have no means of assigning the initial density of any of them.

Scientific Terminology and its Annexation.

NATURE has so consistently maintained the purity and accuracy of English scientific nomenclature, and its occasional leading articles on the subject have been of such great interest and assistance, that I venture to point out the insidious annexation of scientific terms to denote a commercial product.

'Ethyl' is the latest offender; the article in question being a petrol or benzol mixture to which is added a small proportion of an anti-knock substance purporting to be lead tetra-ethyl.

I presume there is not a practicable legal remedy, and one would hesitate to adopt the Shylockian tactics of obtaining a stamped agreement to deliver a quantity of substance at the price of the 'commercial' (misnamed) article, and then holding them to their chemical bond; yet one feels that such a lesson would be richly deserved by those who produce 'Radium,' tooth powder, 'Ozone' liquids, or even call the impure, evil-smelling napthalene (after deleting the 'albo') by the name of carbon.

One would of course not wish to be arbitrary, but such barbarisms as 'saltrates,' etc., are a deliberate counter to our expensive educational schemes.

As regards scientific terminology, one would wish, *pace* the Oxford Dictionary, that 'revolution' and 'rotation' could be logically distinguished. I have always tried to restrict each term to cases where the centre of movement was either outside or inside the body moving, but there are many borderland cases.

The late Prof. Perry, in his usual pungent way, once rejoiced that there was no name for the time fluxion of acceleration. The term 'crement' (from increment or decrement of force) almost suggests itself.

There seems some doubt as to whether the term 'applement,' denoting the difference between a given angle and four right angles, is suitable to take its place with 'supplement' and 'complement' in their usual connotations. Here, I suppose, the criterion is between the relatively few people who might find the term useful, and the many who would be plagued by it. The same applies to 'cyclon' for a pendular vibration, which is shorter than (or almost an abbreviation of) the late Lord Kelvin's 'cycloidal vibration.'

Eyeglasses and the Microscope.

MICROSCOPISTS who are hampered by wearing eyeglasses (that is, pince-nez) often find that when their work requires reference to books or other objects on the table, the incessant business of taking their glasses off and putting them on wastes time, and is apt to become wearisome. There is a simple way of getting over the difficulty. When the glasses are taken off in order to make way for the microscope, they should not be laid down but should be kept on the head, in which position, being near the fine adjustment and the hand resting on it, they can at once be replaced when wanted. To attach the eyeglasses in this way nothing more elaborate is necessary than a piece of ordinary elastic, the two ends of which are tied, or fastened with hooks, to the frame, preferably the bridge, of the glasses. With the elastic loop round the head, the eyeglasses can be raised on the forehead out of the microscope's way or brought into position for reading with a minimum expenditure of time and trouble.

The Sligo Artefacts.

WE, the under-signed, have examined a representative series of the limestone specimens collected by Mr. J. P. T. Burchell in Sligo, Ireland, and, after a study of the type of flaking and of the forms of these specimens, we are of the opinion that they are of human origin. This view is based upon the various criteria applied to universally accepted implements, and has been reached only after the explanation of the Sligo specimens being due to natural forces has been considered and rejected. This statement is without prejudice to their cultural age.

The Present State of Some Problems in the Theory of Numbers.[1]

By Prof. L. J. MORDELL, F.R.S.

THE theory of numbers, which was called the queen of mathematics by Gauss, the originator of the modern theory, still remains supreme. The present era is pre-eminently one in which she dominates the mathematical world. Her willing, loyal, and devoted subjects include the foremost mathematicians in every land. Their recent achievements bear comparison in difficulty and significance with those of any other period. Their propaganda in the last few years includes a surprisingly large number of thrilling treatises, which deal with most aspects of her conquests, and far exceed in number and importance those dealing with any other advanced mathematical subject. There is no lack of effort to present the most recent developments in as inviting and attractive a form as possible. One need only mention recent books in the last few years by Bachmann, Hecke, Landau, and Feuter. No small part of their subject-matter is closely related to or perhaps had its foundations in one or more of the six problems I have selected for discussion, which are associated with such distinguished names, namely:

1. Euler's Three Biquadrate Problem.
2. Fermat's Last Theorem.
3. The Cubic Indeterminate Equation.
4. Gauss' Class Number Problem.
5. Dirichlet's Divisor Problem.
6. Minkowski's Theorem on the Product of Linear Forms.

Some of these problems are comparatively new, such as (5) and (6), and testify to the wonderful freshness and vitality of the theory of numbers. The age of the others can be measured in centuries, particularly (3), special examples of which have been known for about two thousand years.

Their solutions are in every state of completion or rather incompletion, except perhaps for (3), which I solved a few years ago. Although some progress has been made with most of the others, except (1), they present difficulties which severely tax and seem beyond the powers of present-day mathematics. The slightest advances are made only by the most venturesome and heroic efforts, how much so can be easily appreciated by those who have even the slightest interest in the subject. These advances prove both useful and stimulating in many other fields, and it is difficult to exaggerate their importance and influence in the history of mathematics.

There are many striking features about these problems which have been noticed by all workers in this field. A simplicity of enunciation is combined with the fact that many of its most beautiful and startling results are proved originally in most unexpected and complicated ways. It is generally after many years that the simple and apparently natural method is discovered. It is only then that the proofs can be appreciated by greater numbers, just perhaps as the rough diamond only reveals its beauty after it has been polished and cut.

EULER'S THREE BIQUADRATE THEOREM.

This states that the sum of three biquadrates cannot be another biquadrate unless two of them are zero; *i.e.* if integers a, b, c, d satisfy the equation,

$$a^4+b^4+c^4=d^4,$$

then two of a, b, c must be zero.

It is truly remarkable that this simple theorem, the truth of which was conjectured by Euler more than 150 years ago, has neither been proved nor disproved. Further, it has been found absolutely impossible to make any headway with this problem. Indeed, it would be difficult to mention any other which has yielded so little to the efforts of those who have attempted its solution. Hence only some half-dozen references are to be found in the mathematical literature to papers dealing with it. The most important result known is a numerical verification by Aubry, in 1912, that the theorem is true for $|d| \leq 1040$.

The theorem cannot be extended to four fourth powers, as Norrie in 1911 showed that

$$30^4+120^4+272^4+315^4=353^4.$$

The particular case when one of a, b, c is zero, so that the equation is

$$a^4+b^4=c^4,$$

dates back from Fermat. It is proved by his method of infinite descent, *i.e.* if this equation or the less restricted one

$$a^4+b^4=c^2,$$

admits of integer solutions where abc is not equal to zero, then it must have other integer solutions a_1, b_1, c_1 where $a_1b_1c_1$ is not equal to zero, and where c_1 is numerically less than c. By continuing this process we are led to the existence of a solution wherein c is not zero and is numerically less than some definite number (here 1), and it can be easily verified by trial whether this is so. This example is a particular case of the second problem.

FERMAT'S LAST THEOREM.

This states that if integers x, y, z satisfy the equation

$$x^n+y^n=z^n,$$

where n is a given integer greater than 2, then x or y equals zero.

This theorem was discovered about 1637 by Fermat, who wrote upon the margin of his copy of the works of Diophantos, "I have discovered a truly remarkable proof which this margin is too small to contain." The theorem has attained world-wide celebrity because of the Wolfskell prize of 100,000 marks established in 1907 for the first demonstration of its proof. The prize has not yet been won.

The most important results are due to Kummer who spent a great part of his life upon it. Assuming that n is an odd prime p, which involves no loss of generality, he proved the truth of the theorem for values of n included in certain general classes, *e.g.* when n is not a divisor of the numerator of one of the first $\frac{n-1}{2}$ Bernouillian numbers, B_r being defined as the coefficient of $(-1)^{r-1}x^{2r}/2r!$ in the expansion in ascending power of x of x/e^x-1, and in particular for $3 < n < 100$, though his proof was not complete for a few values of n. It is not known whether the values of n for which Kummer proved his results are infinite in number. Though his papers were written about the middle of the last century, no further important results were obtained until 1909. Kummer and his successors in the discussion of the problem divided it into two cases, according as xyz is not or is divisible by p. The first case is the easiest, and for the theorem to hold for this one, Wieferich showed in 1909 that $2^{p-1} \equiv 1 \pmod{p^2}$, that is, $2^{p-1}-1$ is exactly divisible by p^2.

---

[1] A lecture given to the Manchester Literary and Philosophical Society on Nov. 15, 1927.

The first value of p for which this is true was shown by Meissner in 1913 to be 1093. But Wieferich's theorem is a particular case of the more general one that if r is any prime less than p, then $r^{p-1} \equiv 1 \pmod{p^2}$ if the equation $x^p+y^p=z^p$ holds with xyz prime to p. This was proved for $r=3$ by Mirimanoff, for $r=5$ by Vandiver, and by Frobenius for $r=11$, 17, and when $p \equiv 1 \pmod 6$, for $r=7$, 13, 19. The proofs except when $r=2$ or 3 are very complicated and suggest that the real source of these results is still to be found.

Fermat's last theorem is the most important of all the problems that I shall mention, as the efforts made in attempting its solution led Kummer to discoveries that marked the beginning of the theory of algebraic numbers. This discovery later revealed wonderful and beautiful relations between the theory of numbers, elliptic functions, automorphic functions, and many other parts of the theory of functions of a complex variable.

In no other part of the theory of numbers as in Fermat's last theorem are the investigator and reader called upon to deal with such abstract conceptions, such involved results, many of which are arrived at by a long chain of reasoning; and such general theories, *e.g.* laws of reciprocity, which have their foundations deep in the arithmetical theory. No other problem has been attempted by so many distinguished mathematicians, and very few can have led to such remarkable developments.

Cubic Indeterminate Equations.

This problem is to find the rational values of x, y, satisfying the general equation of the third degree in x, y with rational coefficients, namely,

$$ax^3+bx^2y+cxy^2+dy^3+ex^2 \\ +fxy+gy^2+hx+ky+i=0,$$

i.e. to find the rational points on this cubic curve which it is supposed has no double point, as then the problem is comparatively simple.

It is the oldest of those with which I am dealing, and particular cases of this question have been considered so long as two thousand years ago. Its solution proved intractable until six years ago, when I discovered the general solution, which is now so obvious that it is given in lectures at some universities.

A great deal of what was done on this question for many years can be explained in a few sentences. Any straight line meets the curve in three points. If two of these points are rational, the third is found from a simple equation, so that its co-ordinates will certainly be rational. In particular the tangent to the cubic at a rational point will meet it in another rational point.

Now suppose we have already found, perhaps by trial, n rational points on the curve say P_1, P_2 . . . P_n, *e.g.* if $x^3+y^3=9$, $x=2$, $y=1$ is an obvious point. The tangent to the curve at P_1 will meet it again in another rational point P'_1, distinct from P_1 unless P_1 is a point of inflexion. So the tangent at P'_1 meets the curve in general in another point P''_1, etc., and we may expect to find an infinite number of rational points starting from P_1, though it is conceivable that we may find only a finite number of points forming a closed polygon. Similarly, we may expect to find an infinite number starting from P_2 if P_2 is not included in the group arising from P_1, and so for P_3, etc. But we can find another rational point, $Q_{1,2}$ from the intersection of the line $P_1 P_2$ . . . and the curve. We may now either draw a tangent to the curve at $Q_{1,2}$, or draw the secants joining $Q_{1,2}$ and the points P_2, P_3, etc., and find their intersections with the curve.

Clearly, in this way, we can find in general an infinite number of other rational points by starting from n known rational points, say primary points for short. From the time of Fermat onwards, mathematicians had to content themselves with doing little more than deriving for special equations explicit formulæ for the co-ordinates of the points found from one or more given ones, *e.g.*: for

$$ax^3+by^3=c,\ y^2=px^3+q.$$

Even prizes established by learned societies led to no solution.

Finally, I showed that all the rational solutions of the general equation could be found from a finite number of primary ones by drawing tangents and secants as above. In other words, the method of infinite descent gives all the solutions; and there is now no theoretical difficulty in finding them.

Gauss' Class Number Problem.

Let $-D$ be a given negative number and let $ax^2+bxy+cy^2$ be any quadratic form of determinant $-D$, *i.e.*, a, b, c are any integers for which $b^2-4ac=-D$. This requires that $D \equiv 0, 1 \pmod 4$, and then an infinity of integers a, b, c, can be found, and so an infinite number of quadratic forms of given determinant $-D$. It is a classic and elementary theorem that all these quadratic forms can be derived from a finite number, $H(D)$ say, by means of a linear transformation with integer coefficients and determinant unity. It was conjectured by Gauss more than 125 years ago that there are only a finite number of values of D for a given $H(D)$. This has not yet been proved, though a formula and many recurring formulæ are known for $H(D)$. Hecke, making use of an unproved hypothesis about the zeros of a function analogous to the Riemann Zeta function, has given a simple proof. But I wish to deal more particularly with what would appear to be the very simple case when $H(D)=1$. This is so for $D=3, 4, 7, 8, 11, 12, 16, 19, 27, 28, 43, 67, 163$. It is easily verified that for any others, D must be a prime of the form $8n+3$. It was shown in 1911 by Dickson that there is no other value of D less than 1,500,000.

It may seem surprising that the truth of the conjecture about $H(D)=1$, is equivalent to the fact that the formula $z^2+z+2n+1$ gives only prime numbers for the integers z satisfying $0 \leq z \leq 2n-1$ as was proved by Rabinovitch (Rainich), and this is easily verified for $D=43, 67, 163$, when $n=5, 8, 20$.

It is also equivalent to the statement that the only solutions in non-negative integers of

$$yz+zx+xy=D=8n+3$$

are given by

$$(x, y, z)=(0, 1, 8n+3), (1, 3, 2n), (1, 1, 4n+1),$$

and those derived from these by permuting x, y, z.

Neither of these simple facts has, however, proved of use in proving the theorem.

DIRICHLET'S DIVISOR PROBLEM.

The number of divisors $d(n)$ of a given integer n is a function of n which changes very irregularly with n, and is really the number of positive integer solutions of $xy=n$. If n is a prime number $d(n)=2$, while if $n=p^a q^b r^c \ldots$ where $p, q, r \ldots$ are different primes

$$d(n)=(a+1)(b+1)(c+1) \ldots.$$

But though $d(n)$ does not depend so much upon the magnitude of n as upon its form, it is different with

$$d(1)+d(2)+ \ldots d(n).$$

This really represents the number of positive integer solutions of $xy \leq n$, *i.e.* the number of points with positive integral co-ordinates lying in the area bounded by the rectangular hyperbola $xy=n$ and the lines $x=1$, $y=1$, including the boundary in the area. The irregularities are smoothed out as it were, in the sum. Dirichlet showed in 1849 that $d(1)+d(2)+ \ldots d(n)=n \log n+(2\gamma-1)n+R(n)$ where $\gamma=0{\cdot}577 \ldots$ is Euler's constant, and $R(n)$ the remainder or error term is less numerically than a constant multiple of $\sqrt{n}$. This is expressed by $R(n)=O(\sqrt{n})$. For many years this was thought to be the best approximation to $R(n)$. Voronoi proved, however, in 1903, that $R(n)=O(\sqrt[3]{n} \log n)$. Van der Corput showed next that $R(n)=O(n^a)$ with $a=\frac{1}{3}$. This result was arrived at in many different ways, arithmetical, geometrical, by the real variable, and by the complex variable. These all led to $a=\frac{1}{3}$ and seemed to suggest that $O(\sqrt[3]{n})$ was the best approximation to the error term; though it was known from Hardy's work of 1915 that in the error term, the index $a \geq \frac{1}{4}$. Wonderful to relate, Van der Corput showed in 1922 by an exceedingly difficult and complicated method that $a<33/100$. Simpler proofs have since been given by Littlewood, Walfisz, and Landau for the slightly less precise result $a \leq 37/112$.

This extraordinary result appears not to be final; but to have arrived at it is one of the most startling achievements of the present day. The problem is one which has made the greatest demands upon many branches of mathematics. The most delicate questions of convergence, of the theory of functions, and the most adept manipulation of inequalities are all required.

In this problem, as opposed to the others, it is the methods of the analytical theory of numbers which have proved most successful. The most important stage in the proof depends upon Weyl's method of finding upper limits for large values of n to sums such as

$$\cos(f(1))+\cos(f(2))+ \ldots \cos(f(n)).$$

These approximations have also played a vital part in Waring's problem and in the recent theory of the Riemann Zeta function.

MINKOWSKI'S THEOREM ON THE PRODUCT OF LINEAR FORMS.

This is the most recent of these problems, but it has features that mark it out as a worthy companion to those that have preceded it.

Let

$$\begin{aligned}
L_1 &= a_{11}x_1+a_{12}x_2+ \ldots a_{1n}x_n-c_1,\\
L_2 &= a_{21}x_1+a_{22}x_2+ \ldots a_{2n}x_n-c_2,\\
&\ldots\ldots\\
L_n &= a_{n1}x_1+a_{n2}x_2+ \ldots a_{nn}x_n-c_n,
\end{aligned}$$

be n linear non-homogeneous forms where the a's and c's are any real constants subject to the restriction that the determinant $|a_{rs}|=1$, which it may be noted in no wise detracts from the generality of the following theorem. Then it is supposed that there are integer values for $x_1, x_2, \ldots x_n$, for which the product $|L_1 L_2 \ldots L_n| \leq 2^{-n}$.

The proof for $n=2$ was first given by Minkowski. Remak has given another, and I am now publishing one which proves it in a very simple way. But a different state of affairs arises for $n=3$. Remak gave in 1921 an extraordinarily complicated and intricate proof in fifty pages. It depends upon the arithmetic theory of the definite ternary quadratic, and involves ideas closely allied to those occurring in the problem of the closest packing of spheres. Unfortunately, it appears to be exceedingly difficult to extend the proof to the case $n=4$, and it is not known whether the theorem is true for $n \geq 4$, although it seems very likely. It is very rarely that the proof of the generalisation of a question to n dimensions proves so unattainable, especially when in similar questions, for example, in dealing with linear forms in which $c_1=c_2=\ldots c_n=0$, the results for n variables are proved as easily as for two.

It is fairly certain that in due course a very simple general proof will be found, making the truth of the theorem almost intuitive. Such a one could be found by generalising to n variables the simple theorem that if $|a| \leq 1$, $|b| \leq 1$, there is a range of values of width at least two for x for which

$$|ax^2+bx| \leq 1.$$

Neanderthal Man a Distinct Species.[1]

THE fossil crania of the extinct members of the human family have been described and measured by many investigators; but it has long been recognised that there were important lacunæ in our information that had to be made good, and a lack of uniformity in the methods of measurement. Dr. Morant has rendered a very useful service to anthropology by himself measuring all the available crania and providing a complete and uniform treatment of the series in accordance with the refined mathematical methods of Prof. Karl Pearson.

How valuable and important such statistical investigations can be was shown in Dr. Morant's first memoir in this series, in which he provided a mathematical confirmation of Testut's opinion that the Chancelade skull (found in the Magdalenian deposits in the Dordogne thirty-eight years ago) conformed to the racial type of the modern Eskimo, a view that has been so vigorously championed in recent years by Prof. Sollas, and many years ago, in the face of vigorous opposition, by Sir William Boyd-Dawkins.

The second memoir, dealing with the series of Neanderthaloid skulls, is particularly valuable—for providing exact data and the careful investigation of the measurements and interpretation of their meaning. At the present moment, when doubt is once more being cast on the validity of the species *neanderthalensis*, it is important to get Dr. Morant's emphatic corroboration of our morphological conclusions. He informs us that the available measurements of the skulls associated with the Mousterian phase of culture in Europe and Palestine indicate a remarkable homogeneity of type, between which and all modern racial types there is a distinct hiatus, which may be taken to indicate a specific difference. "Some modern races resemble the Neanderthaloid type more closely than others do, but there is no race, or group of races, which is particularly distinguished in that way." "The working hypothesis, that Mousterian man is equally related to all races of *H. sapiens* would seem to be the safest to adopt in the present state of our knowledge. In that case it is impossible to decide whether *H. neanderthalensis* has been a stage in the direct line of descent or not."

With these conclusions most anatomists would agree, with the qualification that the many signs of specialisation in the skull and teeth as well as in the limb bones are fatal to the suggestion that *H. neanderthalensis* could have been in the direct line of descent.

In his recent Huxley lecture, however, Dr. Aleš Hrdlička has questioned (NATURE, Nov. 19, p. 750) the validity of the specific distinction of Neanderthal man, an issue which most anatomists imagined to have been definitely settled by the investigation of Schwalbe in 1899, and the corroboration afforded by the work of Boule and a host of other anatomists. It will be remembered that when the original Neanderthal skull was found, Prof. William King (in 1864) suggested it was a distinct species, if not even a distinct genus, but Huxley opposed this claim and got his way. Thirty-five years later Schwalbe, with ampler material and modern criteria, made out a good case for the reality of the specific distinction, which the discoveries of the skeletons at La Chapelle-aux-Saints, La Quina, La Ferrassie, and elsewhere in 1908 and the succeeding years seemed to put beyond all question.

It is the way of true science constantly to submit to scrutiny the foundations of its theoretical views —a discipline to which a restive anthropology is not always willing to submit. The only justification for re-opening the problem of the status of Neanderthal man would be afforded by new evidence or new views, either of a destructive or constructive nature. I do not think Dr. Hrdlička has given any valid reasons for rejecting the view that *Homo neanderthalensis* is a species distinct from *H. sapiens*. Dr. Morant's important memoir comes at a very appropriate time to buttress the generally accepted view against such criticisms as Dr. Hrdlička's.

G. ELLIOT SMITH.

A Biometric Study of Neanderthaloid Skulls and of their Relationships to Modern Racial Types" *Annals of Eugenics*, vol. 2, Parts III. and IV., October 1927. Issued by the Francis Galton Laboratory for National Eugenics, University of London. 25*s*. net.

Obituary.

MR. LEON GASTER.

WE record with great regret the death of Mr. Leon Gaster, who passed away after a brief illness on Jan. 7. Mr. Gaster's chief work was the founding of the Illuminating Engineering Society, of which he had been honorary secretary since its birth in 1909. A year earlier he had founded the *Illuminating Engineer*, the official organ of the Society, which he edited up to the date of his death. A very sad feature was the fact that his death occurred shortly before the issue of a special number of his journal, celebrating its twentieth anniversary.

Mr. Gaster was a member of many scientific and technical committees, amongst which may be mentioned the Home Office Departmental Committee on Lighting in Factories and Workshops, the Illuminating Research Committee working under the Department of Scientific and Industrial Research, and various committees of the British Engineering Standards Association concerned with illumination. But his wide interests and enthusiasm led him into many other fields of work. He was keenly interested in the National Safety First Association and in the Association of Special Libraries and Information Bureaux. He was a fellow of the Institute of Journalists, and was in turn honorary secretary and chairman of its Scientific, Trade, and Technical Circle. He was also the honorary secretary of the British

International Association of Journalists, and as such was mainly responsible for the organisation of the International Press Conference in London last year.

Even this list does not exhaust the record of Mr. Gaster's activities. He used to affirm that he was a member of no less than thirty different scientific and technical committees. To every piece of work he undertook he brought boundless enthusiasm and indomitable perseverance. He delighted in meeting and disarming opposition, and few could resist his diplomacy and personal charm. It was, perhaps, in international activities that his special gifts found their chief application. Born in Rumania, educated in Switzerland, and with a wide knowledge of foreign countries, he was at once at home in any international gathering. This knowledge stood him in good stead in connexion with his work on the International Commission on Illumination, and in his conduct of the affairs of the British International Association of Journalists.

Mr. Gaster's foresight and sagacity, especially displayed in connexion with illuminating engineering, were remarkable. He had a genius for the correlation of different fields of scientific work and for discovering opportunities for joint effort which few would have perceived. He used to describe his occupation humorously as a 'committee promoter,' but he also found time for a considerable consulting engineering practice, where his knowledge of the world and powers of diplomacy proved quite as valuable as his technical skill. He was a man who made friends by instinct, and was equally well known in journalistic and scientific circles. It is no exaggeration to say that his name was known all over the world. His early death—in spite of his achievements he was only fifty-five years of age—will be widely regretted and his loss severely felt.

WE regret to announce the following deaths:

Dr. Emil Bose, formerly of the Geological Survey of Mexico and the author of numerous contributions on the Mesozoic of Mexico and the Permian of western Texas, on Nov. 8, aged fifty-nine years.

Prof. C. Diener, professor of palæontology in the University of Vienna, and a foreign correspondent of the Geological Society of London, well known as the editor of the "Fossilium Catalogus," on Jan. 6, aged sixty-five years.

Sir Dyce Duckworth, Bart., president of the Clinical Society of London from 1891 until 1893 and *correspondant étranger* of the Paris Academy of Medicine, on Jan. 20, aged eighty-seven years.

Mr. E. Kay Robinson, well known as a writer and lecturer on natural history topics, on Jan. 20, aged seventy-two years.

Prof. F. L. Washburn, professor of entomology at the University of Minnesota, and State entomologist from 1902 until 1918, on Oct. 15, aged sixty-seven years.

Dr. Israel C. White, State geologist for West Virginia since 1897, in which year he was a vice-president of the American Association for the Advancement of Science, on Nov. 24, aged seventy-nine years.

News and Views.

PROF. ARTHUR HUTCHINSON, who has been elected Master of Pembroke College, Cambridge, to fill the vacancy caused by the sudden death of Dr. Hadley, shares with Prof. Seward the honour of combining the offices of Master of his College and professor of a department of science in the University. Prof. Hutchinson was educated at Clifton (1879) and Christ's College, Cambridge (1884), graduating in 1888 with a first class in both parts of the Natural Sciences Tripos, having taken chemistry as his subject in Part 2. His first paper, published in 1889, was the result of work in collaboration with M. M. Pattison Muir "On a Cubical Form of Bismuthous Oxide." He next studied in Germany at Munich and at Würzburg, taking his Ph.D. at the latter University and carrying out research under Emil Fischer on the reduction of aromatic amides. Returning to Cambridge, he worked with W. Pollard on "Lead Tetra-Acetate and the Plumbic Salts," publishing the results in 1893 and 1896. In 1895, the professor of mineralogy appointed him demonstrator of mineralogy, and under this title for many years he gave almost all the lectures for the first year course in mineralogy and crystallography. It was not until 1923 that the University appointed him lecturer in crystallography. He eventually succeeded to the professorship after the death of Prof. Lewis in 1926.

PROF. HUTCHINSON'S connexion with Pembroke College dates from his election to a fellowship in 1893. He held the office of assistant-tutor from 1900 until his election as president of the College in 1926. In the meantime he had served the University on many boards, and was secretary of the General Board of Studies from 1920 until 1925. During the War, he carried out tests for the Admiralty on gas helmets, and for this and other services was awarded the O.B.E. He was president of the Mineralogical Society from 1921 until 1924, and was elected a fellow of the Royal Society in 1922. Lectures and college work left little time for scientific research, yet from 1900 to 1910 no year passed without his making some notable contribution to mineralogy, and in addition he prepared the section on mineralogical chemistry for the *Annual Reports of the Chemical Society* from 1905 until 1913. His first purely mineralogical paper, "On Stokesite, a New Mineral Containing Tin, from Cornwall," was a remarkable example of a complete chemical and physical determination made on a minute amount of material. This was followed by papers on the chemical composition and optical characters of chalybite, a study of the diathermancy and optical characters of antimonite, and on the composition of lengenbachite. More recent important contributions are on the stereographic and gnomonic projections and on various graphical methods for solving problems which arise in the course of mineralogical determinations. The stereographic protractor and the 'universal' goniometer, both of which Prof. Hutchinson designed, have proved of very great utility in the many laboratories in which they have been introduced.

At the recent meeting of Council of the Royal College of Veterinary Surgeons, a signal honour was conferred on Sir John McFadyean, late Principal of the Royal Veterinary College, London, when he was awarded the diploma of honorary associate of the Royal College of Veterinary Surgeons, an honour only once before conferred on a British veterinary surgeon. In making the presentation, the president, Lieut.-Colonel J. W. Brittlebank, referred to the fact that Sir John, who qualified as a member of the College in 1876, and had taken the degrees in medicine and science at Edinburgh shortly afterwards, had been Principal of the Royal Veterinary College since 1892, and a member of the Council of the Royal College of Veterinary Surgeons since 1893, being now the 'father' of the Council. He was a member of the Royal Commission on Tuberculosis appointed in 1901, which refuted Koch's contention that bovine tuberculosis was rarely if ever communicable to man to any serious degree. He also served on the departmental committee appointed to inquire into contagious abortion, 1905, and on many similar inquiries. Specialising at first in veterinary anatomy, McFadyean turned to the study of pathology, and his reputation as a veterinary pathologist and bacteriologist is now world-wide. His special method of staining blood films for the diagnosis of anthrax came into universal application, and his contributions into the elucidation of the problems raised by such diseases as tuberculosis, blackquarter, contagious abortion, and Johne's disease have made his name famous. He is the editor of the *Journal of Comparative Pathology and Therapeutics*, and the author of text-books on the anatomy of the horse and comparative anatomy. In 1905 he was knighted for his outstanding services to veterinary science and was also made an honorary LL.D. of the University of Aberdeen. He was president of the Royal College of Veterinary Surgeons from 1906 until 1910, and of the tenth International Veterinary Congress held in London in 1914.

The Council of the Institution of Electrical Engineers has made the seventh award of the Faraday Medal to Prof. J. A. Fleming, who has recently retired from the chair of electrical engineering in the University of London. This Medal is awarded by the Council of the Institution not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution. Prof. Fleming is well known as the inventor of the first thermionic valve, and has played a notable part in the development of many applications of electrical science.

Two distinguished octogenarian men of science—Sir Robert Elliott-Cooper, K.C.B., and Sir John Isaac Thornycroft, F.R.S., on the civil and marine sides of engineering respectively, celebrate their birthdays next week. The former enters on his eighty-fourth year, having been born at Leeds on Jan. 29, 1845. Many railway and allied projects have engaged his activities both at home and overseas, establishing notable progress in the Victorian era. Sir Robert succeeded Prof. Unwin in 1912 as president of the Institution of Civil Engineers, and a portrait of him hangs there.

Sir John Thornycroft, the eldest son of Thomas and Mary Thornycroft, was born in the Via Felice, Rome, on Feb. 1, 1843, and thus enters on his eighty-sixth year. Educated in early life at private schools, he derived much mechanical training at home, as well as skill in the drawing arts. When eighteen years old he constructed a small steam launch, the *Nautilus*, the first steam craft on the Thames that attained enough speed to keep up with racing crews. A period of intensive training and study followed at Jarrow-on-Tyne, in the engineering department of the University of Glasgow, and at Govan. In business at Chiswick, he became a builder of torpedo-boats, and is justly regarded as the pioneer in the construction of that form of high-speed craft. In 1903 Messrs. Thornycroft and Co. transferred their shipbuilding yards to Southampton, whilst later, important motor works were set going at Basingstoke. Experiments with hydroplanes were begun in 1908, culminating in the remarkable craft known as coastal motor-boats, well remembered in the Navy for their service during the War. Sir John was elected a fellow of the Royal Society in 1893.

On the occasion of his visit to London to receive the Symons Gold Medal of the Royal Meteorological Society, Dr. Hugo Hergesell, the Director of the Prussian Aerological Observatory at Lindenberg, delivered a brief address, selecting as his subject the observation of cloud with special reference to the safeguarding of aviation. Lindenberg Observatory is not only the central observatory in Germany for the scientific investigation of the upper air, but is also the headquarters of that branch of the meteorological service which is charged with the issue of weather reports and forecasts for aviation. Soundings of the lower 3000 metres are made at the Observatory twice a day as a matter of routine, kites, captive balloons, or kite balloons being used to lift the reading instruments, according to the wind conditions prevailing at the time. These three different methods of levitation make it practicable to obtain soundings under almost all meteorological conditions. From the records of temperature and humidity so obtained, the heights and thicknesses of the various cloud layers can be determined, and information on this point is regularly included in the reports broadcast from the Observatory for the guidance of aviators. The difficulties encountered in interpreting the records of the hair hygrometer, in consequence of the deposition of a coating of ice on the hair, were briefly discussed.

Dr. Hergesell then gave some account of the work of the meteorological flight at Tempelhof, which works under the direction of the Observatory at Lindenberg.

This flight is equipped with a Junkers A 20 machine, and ascents are made as frequently as circumstances permit. The pilots attached to the flight have received special scientific training, and a professional meteorologist is carried on each flight as observer. The aeroplane is equipped with a so-called 'gyrorector' or horizontal gyroscope to enable the pilot to determine the direction of the vertical when flying through cloud, as it is well known that in such circumstances the unaided human sense of equilibrium may be entirely at fault. Whenever possible flights are made through the cloud layers, and the flight already has to its credit a large number of ascents made under these difficult conditions. In conclusion, Dr. Hergesell described the use of the inverting range-finder having a base of six metres for the measurement of the heights and movements of clouds, and showed a number of slides exhibiting cloud waves, on which the heights and wave-lengths as determined by such observations were marked.

JUDGING from reports in the daily press on Jan. 24 of the experiments carried out by the engineers of the Bell Telephone Co. on a new loud speaker, it seems clear that their new instrument has a much greater range than any existing loud speaker. Standing on a hill overlooking Hoboken, the engineers of the Company spoke in ordinary tones into a field telephone which was connected with a loud speaker placed on the top of their laboratories in New York, more than a mile distant. After a few seconds their words came back to them as clearly as they had spoken them. They also spoke in this way to the crews of vessels in the River Hudson, which lay between them and the loud speaker. A lady twenty miles away sang a song into a transmitter connected with the loud speaker, and we are told that every tone was clearly reproduced and transmitted. None of the sounds made by the speaker or singer was in the least distorted. The loud speaker reproduces, with no appreciable distortion, tones having vibrations of from 40 to 8000 cycles per second. The excellence of the results obtained is attributed mainly to the high efficiency of the new arrangement of apparatus. It is claimed that more than 50 per cent. of the electrical energy supplied is converted into wave-energy. The diaphragm used in this loud speaker is thinner than a sheet of gold leaf and is little larger than a watch dial. For broadcasting it has many advantages, and it can fill an auditorium with the same volume of sound that sixty men playing instruments would produce. Doubtless a vast crowd can be addressed by its use, and as 'gigantophone,' 'stentorphone,' 'magnavox,' etc., already describe other loud speakers, it will be difficult to find a suitable word to designate it.

THE increasing use of alternating current for supplying electric energy for light and power in Great Britain has led some engineers to think that in the future there will be a diminishing demand for storage batteries. In a paper read to the Institution of Electrical Engineers on Jan. 5, however, Mr. E. C. M'Kinnon gives several reasons for thinking that the demand will increase. New and novel applications for storage batteries are continually arising. They are used for motor-cars and for industrial electric vehicles, and are of great value for helping supply stations to maintain their pressures during peak loads. They are a necessity for submarine vessels. They are also most useful for alternating current automatic plants, for radio beacon equipments, and for broadcasting. The Post Office, however, is the largest user of storage batteries. The gradual adoption of automatic telephones is rapidly increasing the electric power required for the exchanges. It is estimated that this year the ampere-hour capacities of the batteries in the London area alone will be 627,000, with an estimated discharge rate for a nine-hour day of 2000 kilowatts. An official estimate is that by 1936 the capacity of the batteries installed in Great Britain will have increased from the present value of 28,000 kilowatt hours in nine hours to 100,000 kilowatt hours in nine hours. In thirteen or fourteen years there will be about 120 automatic exchanges in London alone, requiring some 21,000 horse-power for six hours to operate them. A very large quantity of lead is used annually in Great Britain for making accumulators. In 1926 it amounted to 247,000 tons, or nearly one-sixth of the total world production of 1,600,000 tons. There is practically no lead in South America and, if we exclude Burma, in Asia. The United States produces 500,000 tons per annum. The combined total annual output of Spain, Mexico, and Canada is about 340,000 tons. Production, however, is largely controlled by demand, and so it is unsafe to assume that the price of lead will rise in the future.

SENSATIONAL claims have recently been made in the *Daily Express* with regard to the possibility of increasing the normal yield of cereal crops from three to five times by means of transplanting the seedlings at a very early stage in development. A machine, invented in Germany, is said to distribute 12,000 seedlings per hour at the rate of about one per square foot, the resulting plants tillering very freely, each producing thirty to forty stems or more. The quantity of seed needed is one-thirtieth or less of that generally used, and the grain is said to be superior in quality to that usually obtained. The method of transplanting has been in use in China for thousands of years, but there hand labour is extremely cheap and circumstances have demanded the most intensive cultivation possible. Under European conditions, labour is so expensive that the saving in cost of seed is negligible compared with the increased labour costs.

THE two main principles underlying this transplanting method are increased root development due to transplanting, and increased tillering allowed by the extra space per individual plant. The former result can be obtained less expensively by the adoption of special methods of surface drilling with machines adapted for the purpose. As regards the second point, it is generally accepted that too thin seeding fails to give maximum crops per acre, and very careful comparative tests would be necessary to prove whether this is also the case after transplantation or not. One great danger under field conditions in the uncertain climate of England would be in that of drought after transplanting, as a few days of fine weather in the early autumn might be sufficient to ruin acres of plants. As to the effect on the yield, it is quite possible to get a heavy increase on a small area under special conditions of cultivation and soil preparation, but it is far more difficult to maintain the same level of increase over large areas which cannot receive such particular treatment. While it is to be hoped that the method will receive full investigation, it would be unwise to raise the hopes of agriculturists until the experimental results are known.

THE next International Mathematical Congress will be held at Bologna on Sept. 3-10. Since the War, previous congresses have been held at Strasbourg in 1920 and Toronto in 1924, but the Bologna meeting will be the first since the War that will be strictly international in character, its two predecessors having been restricted as to membership to subjects of allied or neutral nations. The Italian Prime Minister takes great interest in the Congress and has accepted the office of honorary president. Arrangements are actively proceeding for the various sections of pure mathematics and applications of mathematics to economics and to scientific and technical problems. In addition, excursions are being proposed for visiting the art treasures of Florence and Ravenna and some of the principal hydro-electric plants of Italy. Prof. Pasquale Sfameni, rector of the University of Bologna, is organising president, Prof. S. Pincherle is president of the executive committee, and the general secretary is Prof. Ettore Bortolotti, Via Zamboni 33, Bologna. This is the second congress held in Italy, the previous one being at Rome in 1908.

THE fifteenth International Geological Congress will be held in South Africa in 1929, and the date of the inaugural meeting in Pretoria is to be during the fortnight following July 29. The special subjects provisionally proposed for discussion are: (a) magmatic differentiation; (b) pre-Pleistocene glacial periods; and (c) the stratigraphy, palæontology, and world distribution of the Karroo system. In the past the Congress has published several economic studies of great value, and on this occasion the subject suggested, "The Gold Resources of the World," is particularly appropriate. It is proposed to organise two long excursions before the session opens: one to illustrate the more attractive features of the geology of the Cape, concluding with a visit to the diamond mines and to the Dwyka glacial deposits near Kimberley; and the other to provide an opportunity of making a detailed study of the diamond pipes and of the Witwatersrand goldfield. During the session itself there will be excursions around Pretoria, to Johannesburg, and to the platinum field of Rustenburg. Three alternative excursions are provisionally proposed to follow the session: (a) to the Vredefort granite dome; (b) to the Drakensberg escarpment and the asbestos deposits of Barberton; and (c) to the Stormberg, for the study of the Karroo system. After the first two of these a long excursion to the Bushveld Complex is to be held, and, if it be possible, an alternative tour will be arranged, bringing in the Victoria Falls, the Wankie coalfield, and the Bulawayo district. Communications should be addressed to The General Secretary, XV. International Geological Congress, P.O. Box 391, Pretoria.

AN International Geographical Congress, under the auspices of the International Geographical Union, will open in London on July 14 and transfer to Cambridge on July 17, where the scientific and business transactions will continue until July 25. General Vacchelli, president of the Union, will preside over the Congress. The meetings in London will be mainly ceremonial, and will include receptions at the Royal Geographical Society, the Science Museum, and, by the Lord Mayor and Corporation of the City, at the Guildhall. At Cambridge there will be a reception by the Vice-Chancellor of the University and a dinner and reception offered by the Government. The work of the Congress is to be divided into six sections: (*A*) mathematical, (*B*) physical, (*C*) biological, (*D*) human, (*E*) historical, and (*F*) regional. Three subjects have been specially selected for discussion: (1) The problem of rural occupation, including the origin and causes of the agglomeration or dispersion of rural habitation, and the influence of natural conditions and racial traditions. (2) The International map on a scale of one to a million, which is making steady progress in many countries. (3) The study of pliocene and pleistocene coast and river terraces with the object of determining the existence of constant levels, if they exist, and of fixing their succession. The Committee will also welcome communications on any subject, and particularly the following: (4) Variation of climates, (5) flora and fauna of high mountains, (6) the map of internal drainage areas on which M. E. de Martonne is preparing a memoir for the basis of a discussion.

FIVE mornings will be devoted to meetings of the sections of the Congress, and several afternoons to more general geographical topics. Exhibitions are being arranged of the Carte du Monde Internationale au Millionème, the maps of the Ordnance Survey, and the Geographical Section of the War Office. At the end of the Congress a number of excursions, of two to five days' duration, will be arranged. These will be by motor coach, and will enable foreign visitors to see various parts of England and Wales. Arrangements have been made for reduced fares for members travelling to London and Cambridge to attend the Congress. The chairman of the executive committee is Sir Charles Close and the secretary is Mr. F. Debenham. Applications for membership (£1) and all inquiries should be addressed to The Secretary, International Geographical Congress, Caius College, Cambridge.

IN 1600 the reindeer was to be found in all parts of the Scandinavian peninsula. Now it is extinct as a wild animal in Sweden and Finland. In *Naturen* for for November, Carl Schulz tells the melancholy tale of the war of extermination that has been waged against it in Norway. Successive "inventions of the devil," as various true sportsmen have called them, from the flint-lock to the latest long-distance rifle, have gradually diminished the numbers of this interesting creature. At the beginning of this century a complete close time was enacted from 1902 to 1906. The herds increased and the slaughter began again, so that to-day the situation is as in 1901. There is no economic reason for this destruction: 72 per cent. of Norway is uninhabitable fell. Surely there is room enough for the wild deer. New laws, says the author, are useless so long as they are neither obeyed nor enforced.

Commdr. R. E. Byrd, U.S.N., who in 1926 flew from Spitsbergen to the Pole, is planning an expedition to the Antarctic. The *Geographical Journal* for January states that he proposes to enter the Ross Sea in December this year and to make his base at the Bay of Whales on the Ross Barrier, where relatively calm weather may be expected. Dog teams will be used to lay out four or five bases 100 miles apart towards the Pole. These will be used in case of mishap on a polar flight which is to be one of the main features of the expedition. Ten scientific workers will accompany the expedition, and the remainder of the party will consist of men with previous Arctic experience. Eskimo dogs, aeroplanes, and snow tractors will be taken. The flying machines will include one large tri-motor monoplane, similar to that used in Com. Byrd's recent trans-Atlantic flight, and one or two single-engine monoplanes. The hope of taking off from the open sea off the Barrier is a doubtful project since ice will almost certainly form on the floats. A trans-Continental flight to the Weddell Sea will probably not be attempted on this expedition, but aerial photography is proposed in the region of Edward Land and in the unknown region to the east of it, where no ship has been able to penetrate.

The Galton Anniversary Dinner will be held at the Rembrandt Hotel, Brompton Road, on Thursday, Feb. 16, at 7.15 P.M. The Galton Lecture will be delivered by Mr. C. J. Bond, who will take as his subject, "The Distribution of Natural Capacity in the Population and the Need for National Stock-taking."

At the ordinary meeting of the Institution of Electrical Engineers to be held on Thursday, Feb. 2, at 6 P.M., a portrait in oils of Mr. Ll. B. Atkinson, past president of the Institution, will be formally presented to the Institution by the Cable Makers' Association. The portrait was painted by Mr. G. Harcourt, R.A.

It is announced in *Science* that Dr. H. J. Muller, professor of zoology at the University of Texas, has been awarded the 1000 dollars prize of the American Association for the Advancement of Science for his paper on "The Effects of X-radiation on Genes and Chromosomes," read at the recent Nashville meeting of the Association.

The King has conferred the rank of Honorary Knight Commander of the Order of St. Michael and St. George on Dr. A. Castellani, Director of Tropical Medicine at the Ross Institute and Hospital for Tropical Diseases, Putney Heath. Dr. Castellani is well known for his discoveries in connexion with sleeping sickness, yaws, and other tropical diseases, and is at present in the United States at Tulane University, New Orleans. He is also to be congratulated on the announcement made last week that the King of Spain had conferred on him the Grand Cross of the Order of Civil Merit.

The following have been elected officers of the Royal Meteorological Society: *President*, Sir Richard Gregory: *Vice-Presidents*, Sir Gilbert T. Walker, Col. A. J. H. Maclean, Mr. R. Arnison, Mr. I. D. Margary; *Treasurer*, Mr. F. Druce; *Secretaries*, Dr. C. E. P. Brooks, Commander L. G. Garbett, Dr. A. Crichton Mitchell; *Foreign Secretary*, Mr. R. G. K. Lempfert; *New Members of Council*, Mrs. C. J. P. Cave, Mr. F. Entwistle, Lieut.-Col. Ernest Gold, Dr. J. S. Owens, Mr. W. M. Witchell.

The following have been elected officers of the Royal Microscopical Society for the ensuing year: *President*, Mr. J. E. Barnard; *Vice-Presidents*, Dr. R. S. Clay, Dr. W. E. Cooke, Dr. J. W. H. Eyre, Dr. James A. Murray; *Treasurer*, Mr. Cyril F. Hill; *Secretaries*, Prof. R. Ruggles Gates, Dr. Clarence Tierney; *New Members of Council*, Dr. J. D. Coales, Dr. G. M. Findlay, Mr. J. Rheinberg, Mr. E. J. Sheppard; *Librarian*, Mr. S. C. Akehurst; *Curator of Instruments*, Mr. W. E. Watson Baker; *Curator of Slides*, Mr. E. J. Sheppard.

The Report of the Council of the Zoological Society of London states that the number of visitors to the Society's Gardens during the past year reached the record total of 2,158,208, an increase of 101,062 as compared with the previous record in 1924 (the year of the British Empire Exhibition at Wembley). The receipts for admission for the year amounted to £68,433, actually showing a decrease of £793 as compared with the receipts for 1924. This is partly due to the increased number of fellows, who were responsible for the admission of 39,964 visitors by their signatures and the distribution of their tickets; also 40,192 children were admitted free under an arrangement with the *Daily Sketch*. The number of visitors to the Society's Aquarium during the year was 458,936, and the receipts amounted to £18,293, an increase of £1050 as compared with the previous year.

Prof. Henry Fairfield Osborn, president of the American Museum of Natural History, has been elected president of the American Association for the Advancement of Science for the present year. Vice-presidents of the various sections have been elected as follow: Section A (mathematics), Dr. K. C. Archibald, of Brown University; Section B (physics), Dr. P. W. Bridgman, of Harvard; Section C (chemistry), Dr. C. E. K. Mees, of the Eastman Kodak Laboratory; Section D (astronomy), Dr. J. S. Plaskett, of the Dominion Astrophysical Observatory, Canada; Section E (geology and geography), Dr. Frank Leverett, University of Michigan; Section F (zoology), Dr.

M. F. Guyer, University of Wisconsin; Section G (botany), Dr. C. E. Allen, University of Wisconsin; Section H (anthropology), Dr. Fay-Cooper Cole, University of Chicago; Section I (psychology), Dr. H. C. Warren, Princeton; Section M (engineering), Dr. R. L. Sackett, Pennsylvania State College; Section N (medicine), Dr. A. J. Goldfarb, College of the City of New York; Section O (agriculture), Dr. C. A. Mooers, University of Tennessee; and Section Q (education), Dr. Truman L. Kelley, Stanford University. The 1928 meeting of the Association will be held in New York City.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A research student in the department of protozoology of the London School of Hygiene and Tropical Medicine—The Secretary, London School of Hygiene and Tropical Medicine, 23 Endsleigh Gardens, W.C.1 (Feb. 11). A professor of physiology at Presidency College, Calcutta—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S.W.1 (Feb. 11). An assistant on the higher technical staff of the library of the Science Museum, South Kensington—The Director and Secretary, Science Museum, South Kensington, S.W.7 (Feb. 18). Three assistant lecturers in mathematics in the University of Manchester—The Registrar, University, Manchester (Mar. 1). The Radcliffe Crocker travelling scholarship in dermatology at University College Hospital Medical School—The Dean, University College Hospital Medical School, Gower Street, W.C.1 (Mar. 31). An engineer in charge of workshops in the Research Department, Woolwich Arsenal—The Chief Superintendent, Research Department, Woolwich, S.E.18.

Our Astronomical Column.

SKJELLERUP'S COMET.—Science Service, of Washington, has distributed with a recent *Daily Science News Bulletin* a remarkable photograph of this comet taken at the Lowell Observatory, Flagstaff, in daylight. According to *Popular Astronomy*, it was taken in infra-red light. The coma is very conspicuous, being large and bright, and a fan-shaped tail may be traced for some distance. Dr. C. Hoffmeister at Sonneberg was able to trace the tail to a length of 40° on several mornings at the end of December. The head was invisible, being too near the sun (*Beobach. Zirk.*, No. 2). Mr. R. A. McIntosh, of Auckland, N.Z., sends some interesting drawings of the telescopic aspect of the comet on the morning of Dec. 6. They closely resemble those of Coggia's comet of 1874. There is the same dark space in the middle of the tail, and intersecting paraboloid envelopes. These combine to give the aspect of a bright fan opening out on the sunward side of the head. Stars being shown in the picture, it is possible to deduce a position. This comes out R.A. $16^h\ 26^m\ 51^s$, S. Decl. 51° 9′, at U.T. Dec. 5·646.

BRIGHT METEORS.—Mr. W. F. Denning writes: "Between Jan. 16 and 20, several bright meteors were observed at Bristol by an assistant. It is desirable to obtain duplicate records, as the objects were of decidedly interesting character. The particulars were as follow:

Date.
Jan. 16, $10^h\ 3^m$ P.M.: equal to Jupiter. Path from 61° + 72½° to 38° + 44°, slow motion, bright streak.
Jan. 19, 6 14 P.M.: equal to Sirius. Path from 353° + 63° to 10½° + 50°. Slow. Probable radiant at 314° + 48°.
Jan. 19, 6 48 P.M.: equal to Jupiter. Path from 26° + 44° to 31° − 4°. Slow, bright train. Probable radiant, 195° + 58°.
Jan. 20, 6 40 P.M.: equal to Venus. Path from 300° + 76° to 300° + 36½°. Slow. Long flight. Probable radiant, 120° + 0°."

PHOTOGRAPHIC STELLAR PHOTOMETRY AT ALLEGHENY.—The 31-inch Thaw refractor of Allegheny observatory was designed principally for the purpose of parallax observations, but as it was possible to undertake this work during only a part of each night, the remaining hours of darkness have been utilised for other purposes in order to make the best use of this fine instrument. The most important work which has been carried out is photographic photometry by the extra-focal method. This is especially interesting in view of the fact that hitherto no large telescope has been devoted to this work, since reflectors can conveniently utilise only sharp focus images for this purpose, and extra-focal work has mainly been performed by small refractors uncorrected for photographic rays. The large aperture of the photographic telescope at Allegheny renders it especially useful for photometric work on short period variables, where great speed in exposure is essential. An account of the instrument and methods of work is given in the *Publications of the Allegheny Observatory*, vol. 7, No. 1, together with the results so far obtained for 29 faint Cepheid variables. Details of all the observations are given in each case, as well as light curves based on normal places.

THE ANCIENT ASTRONOMY OF THE MAYAS.—The attempts that have long been made to gain some insight into the scientific knowledge of the Mayas are beginning to bear fruit. Dr. H. J. Spinden contributes an article to the *Scientific American* for January on their system of astronomy, which presumably was derived independently of any systems hitherto known. The zodiac was for them also an 'Animal Circle,' but the animals were quite different from ours; the Pleiades were in the Rattlesnake; the Turtle occupied part of Gemini; they had a Scorpion, but it was adjacent to Gemini.

The Maya gained a considerable knowledge of the planetary movements, and obtained useful cycles, after which configurations repeated themselves. They found the 8-year Venus cycle so far back as the sixth century B.C., and later found the very exact 243-year cycle. Their zodiac is stated to have contained 13 signs, and their year 13 months of 28 days each, a device which many calendar reformers wish to adopt now. It is not stated how they arranged the odd day.

The article states that the Maya adopted in their astronomical records a continued count of days, starting with 613 B.C., similar to the system of Julian days; such a count is of great utility in tracing cycles of recurrence, which were much more difficult to detect among nations that used a lunar calendar. Their instruments for pointing on the stars had V-shaped sights like those used on rifles. Further contributions are promised, and it is evident that these records are of a character likely to repay all the trouble that has been taken in their decipherment.

Research Items.

HESPEROPITHECUS.—The attention of our readers is directed to an interesting statement on this animal published by Dr. W. K. Gregory in a recent number of *Science* (Dec. 16, 1927). As is well known, the specimen is a much worn tooth and therefore very difficult to decipher. Its original description as being a primate was received in many quarters with considerable scepticism. The authorities of the American Museum of Natural History, not content to leave the question in doubt, have made every effort to set it at rest by careful search for further material. As a result it now appears practically certain that the animal is not primate at all and that the tooth in question belongs to a peccary, Prosthenops. Dr. Gregory has paid great attention to the problem, and his considered opinion carries the greatest weight.

STONE CELTS FROM INDIA.—Two recent finds of stone implements are recorded in vol. 22, N.S. No. 3 of the *Journ. and Proc. of the Asiatic Soc., Bengal.* The first is a celt from the Naga Hills which is described by Mr. J. H. Hutton. It is remarkable in that the material, instead of being 'Indian jade,' olivine, serpentine, or similar material, as is almost always the case, is made of fossilised wood. It was found by Mr. G. Heseldin early in 1926 when making a road at Nichuguard at the foot of the Naga Hills. Its measurements are: maximum length 4¾ in., max. breadth 2¾ in., max. thickness ¾ in. It is slightly shouldered—the usual form. As this silicified wood is abundant a few miles north-west of Dimapur, it may fairly be inferred that it was made locally. The second find consisted of two neolithic implements discovered when a tank was being dug at Jamalpur (Monghyr). They are described by Upendra Nath Brahmachari and Shyama Charan Brahmachari. The first implement was found at a depth of ten feet. It is an unpolished celt with sharp, round, cutting edge, both sides of the edge being ground and polished up to a depth of one inch. There is a prominent ridge on one side on the unpolished portion. The second specimen was found at a depth of 15 ft. It is an unfinished celt with a cutting edge slightly curved. One side has been hammered into shape and there is a groove for hafting broken at the top. Both implements are made from the same rock, a fine grained schistose phyllite which occurs about two miles away.

CANCER.—Cancer of the uterus is one of the chief causes of death in middle-aged and elderly women, and the Departmental Committee of the Ministry of Health has issued a useful memorandum (Circular 826) which summarises the present position in respect of diagnosis and treatment. The natural duration of the disease from the first symptom to death is on the average rather less than 2 years. About half the cases when first seen by medical men have already advanced beyond the stage at which surgical operation is possible. Of these inoperable cases, some 10 per cent. can gain some considerable prolongation of life and perhaps be cured by the local application of radium. Of those in whom it is possible to attempt the removal of the growth by operation, at least 10 per cent. die from the necessary severity of the procedure, and about 40 per cent. survive for at least 5 years, most of whom may be looked upon as cured. Cases which are operable can also be treated with radium, which gives no operation mortality and presumptive cure in 40 per cent. On the average, therefore, about 1 woman in 5 who comes to a doctor with symptoms of uterine cancer has a fair prospect of being cured—a position bad enough, but a good deal better than it used to be. The natural progress of the disease being so rapid, it is imperative that the slightest sign of irregular uterine hæmorrhage should be taken seriously and expert advice obtained.

THE FOOD-FISHES OF ST. ANDREWS BAY.—Prof. W. C. M'Intosh ("The Food-Fishes of St. Andrews Bay") has brought together his notes which were published in the *Fishing News* from Aug. 13 to Oct. 29, 1927. These notes were made by the author at intervals over a period of about forty years, and, as he states in the preface, the Bay and its fisheries have been familiar to him for more than eighty years. The actual records begin in 1885 and extend to 1922, but few are made in each year, even at times only a single entry. It is interesting to follow these casual notes, which show the nature and magnitude of the catches at various times. These include plaice, herrings and sprats, cod, haddock, skate and young dabs, lemon-dabs and flounders. Often the contents of the fishes' stomachs were examined. At times sharks, porpoises, and large numbers of sea-birds were caught and duly noted. Apparently there are still many young fishes in St. Andrews Bay, and it is to be hoped that the writer is not too optimistic in his confidence in the permanent abundance of food-fishes in that area.

NORTH AMERICAN DIATOMS.—The second part of "A Synopsis of the North American Diatomaceæ," by Charles Boyer (*Proc. Acad. Nat. Sci. Philadephia*, vol. 79, 1927, Supplement), is now published, the first part having appeared in 1926 in the same publication (vol. 78). This first part contained, in addition to the introduction and classification, the Centricæ and the first division of the Pennatæ (Fragilariatæ). The present part contains the remainder of the Pennatæ (Naviculatæ and Surirellatæ), and as in this group are included the majority of the fresh-water and littoral forms which are more easily collected and more frequently studied than those from the open sea, it is much more complete than the first part. Welcome additions are a good index, and an appendix recording several of those planktonic marine species omitted before. Most of these latter are recorded from La Jolla, California, and from the Gulf of Maine. The two parts together form a valuable guide to North American diatoms, and the author is to be congratulated on the completion of his arduous task, the number of species and varieties in the synopsis being upwards of nineteen hundred.

THE GOLGI APPARATUS OF PROTOZOA.—At least five different types of supposed Golgi bodies have been described in Protozoa and a useful review of them is given by Dr. S. D. King (*Jour. R. Micr. Soc.*, **47**, part 4, 1927). Hirschler (1914) first recorded a Golgi apparatus in Protozoa in the form of osmiophile rings and crescents in the cytoplasm of *Monocystis ascidiae*, and Golgi elements have since been described in other gregarines and coccidia. In all these Sporozoa the Golgi apparatus is in the form of discrete rods and granules, often clumped near the nucleus in the early stages but later spreading through the cytoplasm. Its function is probably secretory, there being evidence to indicate that the lipoid granules of the gametocyte are derived from the Golgi elements. The work of Duboscq and Grassé (1924–27) points to the homology of the Golgi apparatus of herpetomonads and other flagellates with the parabasal apparatus (kinetonucleus). It is suggested that the clear 'space' around the kinetonucleus, which can be stained *intra-vitam* and is therefore not an artefact, may correspond to the chromophobe substance. Grassé considers that the stigma of the euglenoids, which may or may not be coloured, represents the parabasal apparatus. After reference to lipoid cell constituents believed to represent the Golgi apparatus in Opalina and Anoplophrya, a résumé is given of Nassonov's work (1924–25) on the contractile vacuole of ciliates. Nassonov assumes that the permanent osmiophile membrane which surrounds the vacuole secretes the osmotically active substance necessary to the working of the vacuole and pours it into the latter after each successive systole—a secretory activity which is compared with that of Golgi bodies in the gland cells of Metazoa. He figures a ring-shaped Golgi apparatus in relation to the contractile vacuole. Dr. King points out that investigations are required on flagellates such as Bodo and Euglena in which both parabasals and contractile vacuoles are present.

PRAIRIES AND TREE GROWTH.—Various theories have been advanced to explain the lack of tree growth on the prairies. Prof. J. E. Weaver, of the University of Nebraska, has re-examined the problem, and the results of his experiments, as communicated to the American Association for the Advancement of Science, are summarised in a *Daily Science News Bulletin* issued by Science Service, Washington, D.C. His work in tree planting on densely vegetated prairie confirms the observations of other workers in the same field (see Ewing, *Jour. of Ecology*, vol. 12, No. 2, p. 238). The climatic prairie is overcrowded, and there is never enough water and soil nutrients for all species, and consequently the dense mat of vegetation makes the chances of the newcomer very poor. Even when planted in a strip 12 inches wide from which the sod has been removed, trees make little headway. After three years, Weaver found that the trees were only 18 inches high, but with roots 7 feet deep and widely branched. None of the roots extended into the grass sod. In a second row the sod was unbroken, but the grasses were kept cut back, giving the tree seedlings full sunshine but not enough water. Here again most of them were greatly dwarfed. In other rows the trees were left unaided in their struggle with the grasses, and only a few sickly specimens survived. Watering made conditions even worse for the trees, for the resulting vigorous growth of the grasses caused greater overshadowing of the tree seedlings.

THE MISSISSIPPI FLOODS.—A study of the floods of 1927 in the Mississippi basin is the subject of a recent memoir by Mr. H. C. Frankenfield (*Monthly Weather Review*, Supplement No. 29). The lower Mississippi floods, which were disastrous in the spring of 1927, are caused by a wide distribution of rains over the central plains. The waters of the Missouri River above the mouth of the Platte, and of the Mississippi above the mouth of the Wisconsin, do not materially add to the strength of the floods. In comparison with 1922, the previous year of great floods, there was little difference in the rainfall during January and February, but in 1927 there were heavy falls in April in the lower Arkansas valley, while a heavy fall in the Ohio basin in the previous December contributed a good deal to the floods. The probability of such high waters occurring in the near future is not great, although the last great flood was only five years ago. At the same time, Mr. Frankenfield believes that last year's floods did not attain the possible maximum. He calculates the maximum levels as follows, compared with the 1927 level: Cairo, 58 ft. (1927), possible 66 ft.; Memphis, 47 ft. (1927), possible 55 ft.; New Orleans, 27·5 ft. (1927), possible 30 ft. At New Orleans the effect of tides and winds may also be felt. The monograph contains full statistical data and is illustrated with rainfall and other maps.

THE DIFFRACTION OF ELECTRONS.—The experiments of C. Davisson and L. H. Germer on the elastic reflections of electrons from a single crystal of nickel, which were the subject of correspondence in NATURE last year (April 27), are described in detail in the December number of the *Physical Review*. They are remarkable both for the complicated nature of the apparatus and for the significance of the results. The experimental tube contained an elaborate piece of metal-work, consisting essentially of an 'electron gun,' a nickel target, and a Faraday cylinder to collect the reflected electrons, and although the whole was maintained at a pressure which was probably less than 10^{-8} mm. mercury, the constituent parts were capable of movement which allowed the scattered electrons to be examined for distribution both in latitude and azimuth. Those electrons which lost little energy in the process behaved as if they were equivalent to pencils of radiation, except that it was necessary to suppose that the crystal was effectively contracted normal to its surface by an amount depending on the speed of the particles. The corresponding wave-lengths agreed with those required by wave mechanics. It has also been found possible to deduce the structure of the adsorbed films of gas which are present when the crystal is not scrupulously clean, from the additional diffracted pencils to which they give rise, but it appears from a subsequent paper read by the authors at the December meeting of the American Physical Society that there is here some uncertainty in the interpretation of the results.

GAMMA-RAYS FROM POTASSIUM SALTS.—In determinations of the residual radiation of his instruments in the Berlepsch shaft at Stassfurt, Prof. Werner Kolhörster has found an appreciable γ-radiation from 'Hartsalz' ($NaCl$, $MgSO_4.H_2O$, KCl) (*Die Naturwissenschaften*, 16, 28; 1928). Preliminary measurements with iron of mean thickness 3·75 cm. gave a value of $\mu_{Fe} = 0{\cdot}19$ cm.$^{-1}$, so that the rays are harder than those from radium C after filtering through 4 cm. lead, in which case $\mu_{Fe} = 0{\cdot}356$ cm.$^{-1}$ (Kohlrausch). Further measurements with large quantities of sylvine yielded the following values of μ_{Fe} for the thicknesses of iron given in brackets: $\mu_{Fe} = 1$ cm.$^{-1}$ (up to 8 mm.), $= 0{\cdot}35$ cm.$^{-1}$ (8 to 16 mm.), $= 0{\cdot}19$ cm.$^{-1}$ (16 to 60 mm.). The intensity of the radiation per gram of sylvine was equivalent to that from at least 10^{-11} gm. of radium, but separate measurements of the amount of radium in the sylvine showed that the radiation could not be attributed to radium contamination. The investigation of the thorium content of sylvine is being carried out, but there seems little doubt that the γ-radiation is due to potassium. The radiation is proportional to the potassium content, and its hardness suggests the existence also of a very penetrating β-radiation, hitherto unknown, from potassium. The work is being continued, and rubidium and cæsium are also being investigated. There appears to be also a γ-radiation emitted by rubidium.

ACTIVE NITROGEN.—The November issue of the *Journal of the Chemical Society* contains a further account by E. J. B. Willey of his investigations of active nitrogen. This modification of the element has been considered to be atomic, molecular and metastable, and triatomic by various workers, and a brief summary is given in the above paper of each of these views. It was suggested that the luminous phenomena observed with active nitrogen are due, not to the chemically active constituent, but to the recombination of a small proportion of nitrogen atoms produced simultaneously, and Willey has carried out four series of experiments which support this view. The luminosity was destroyed both by heat and by an auxiliary electrical discharge, and it was found that chemically active nitrogen was still present. Willey considers that the non-luminous form of active nitrogen is probably a metastable diatomic or acetylenic molecule with a heat of formation of approximately 45,000 cal./gm.-mol., while the heat of formation of the atomic form is 200,000 to 250,000 cal./gm.-mol. These new views explain satisfactorily various observations which previously appeared to be contradictory.

The Surface Tension of Liquid Carbon Dioxide.—The surface tension of liquid carbon dioxide has been determined by E. L. Quinn over the temperature range 25° to − 52·2°, and the results are given in the *Journal of the American Chemical Society* for November. The capillary rise method was the only one that could be employed owing to the very high vapour-pressure of carbon dioxide at ordinary temperatures. The capillary tube was enclosed in a Pyrex tube of 1 cm. diameter, the carbon dioxide being distilled in before sealing off. The observations were corrected for the quantity of liquid in the meniscus and for the capillary effect of the narrow outer jacket. The surface tension was then calculated, using density values for the liquid obtained by Behn and Jenkin, and extrapolations of Amagat's values for the vapour, an equation being derived for calculation of the density of the saturated vapour between 25° and 0°. From the surface tension results the internal pressure of liquid carbon dioxide was calculated and found to be about the same as that of carbon tetrachloride, toluene, and chloroform, and hence, according to Hildebrand's view of solubility, carbon dioxide probably resembles these liquids in its solvent properties.

Electrical Disturbances in Cables.—Very little progress has been made since Kelvin's time in explaining the curious effects produced by sudden electrical and magnetic storms in the working of submarine cables. All these cables are worked by an earth return circuit. Hence external disturbances can enter the circuit directly from the earth connexions. Some of these disturbances are doubtless due to currents in the earth caused by natural phenomena. Others are artificial and due to the working of other cables and to the earth currents caused by electric railways, tramways, and power stations. The cable companies give much more thought to methods of alleviating these disturbances in their lines than to detecting the causes of them. They have found that the best remedy is to make the earth connexion in deep water at a depth of about 100 fathoms. This is done by taking the earth connexion to a special core insulated inside the cable and connected with the sheath at the desired earthing point. All the high speed Atlantic cables now use sea 'earths' at a suitable distance from the end of the cable. The remaining disturbances, when troublesome, can be swamped by increasing the current. Magnetic storms, however, seem to act on the cable directly by induction. Very high voltages have been observed during these storms between the cable end and the earth. Work is quite impossible during a bad magnetic storm and the cable is earthed at both ends for protection. Fortunately, such storms are rare, and seldom last for more than a few hours. Not infrequently, however, after a severe storm, they recur for several days in succession. Kelvin thought that these storms would give splendid opportunities for scientific observation. But as Mr. Hughes in his paper on submarine cable design, published in the January number of the *Journal of the Institution of Electrical Engineers*, points out, the cable engineers are then very busy and have no time to take observations and make measurements of the disturbances.

Arc Type Electro-Steel Furnaces.—A large number of electro-steel furnaces of the arc type are used in industry. The discovery of stainless iron and steel has given a large and rapidly extending use for electric steel furnaces. One of the difficulties that has to be overcome is to maintain the electrodes at a constant distance apart, notwithstanding the continuous alterations which occur in the circuit. These are mainly due to the alterations that occur during the melting period in the position of the iron and scraps. The liquid charge also bubbles and the electrodes continually burn away. To compensate for these changes the electrodes have to be continually moved. The efficiency of these furnaces and the time required for each charge depends largely on the electrode regulating devices. In *A.E.G. Progress* for November, two types of regulator are described. The first method is the Leonard-Tirrel System. As these furnaces generally employ a three-phase arc, three direct current lifting motors are used to move the electrodes. These motors are controlled in a way similar to that used to keep the voltage of an ordinary alternator constant by means of a voltage regulator. In the second method hydraulic cylinders are employed, the pressure being controlled by means of valves. A water supply under a pressure of about four atmospheres is required and, if necessary, this can be obtained from a special plant. Both these methods are found satisfactory in practice. The position of the electrodes can be controlled by hand at any distance from the furnace; they produce a constant current automatically, and in the event of a failure of the supply voltage both electrodes remain in a fixed position.

Harmonic Curves.—Donkin's harmonograph, designed and constructed in wood by Mr. A. E. Donkin in 1873, was presented by him in 1925 to the Science Museum, where it is exhibited with the mathematical instruments. It is described in the *Proceedings of the Royal Society*, 1874, vol. 22, pp. 196-199. Prof. Tyndall was much interested in the instrument, and at his suggestion Mr. Donkin had a similar instrument constructed by Messrs. Tisley and Spiller. This was exhibited at the Special Loan Collection at South Kensington in 1876. The harmonic curves are drawn by a pen on a paper secured round the surface of a cylinder. By means of two eccentrics, simple harmonic motions are given to the pen and cylinder respectively, the relative number of vibrations being variable by the use of change wheels. Since both pen and cylinder move at once, the curve drawn shows the combination of the two motions. In the second edition (1884) of the book on acoustics written by his father, Prof. W. F. Donkin, previously Savilian professor of astronomy at Oxford, Mr. Donkin added an article on compound harmonic curves (pp. 50-54), illustrated by 21 examples of the curves drawn by his instrument. Some of these curves are included in a printed sheet of 15 curves now issued by him. Expressed in terms of musical intervals, the curves represent: simple tone, octave above, the two combined, fifth, fourth, major third, minor third, major tone, minor tone, sixth, semitone, twelfth, comma, octave out of tune, twelfth out of tune. Copies of the sheet may be obtained at 2*s*. 6*d*. per dozen, post free, from Mr. A. E. Donkin, 5 Sion Hill Place, Bath.

The N.P.L. Primary Standard of Mutual Inductance.

UNDER the heading "British Scientific Gift to Japan," the *Times* recently gave a brief account of a ceremony some fuller details of which may be of interest to readers of NATURE. An absolute standard of mutual inductance was constructed at the National Physical Laboratory in 1907–8 from the designs of Mr. Albert Campbell. The standard was described by Mr. Campbell in 1912, and the value of the coefficient of mutual inductance as found by calculation was given by him as 10017·83 microhenries.

In the early part of 1914, Dr. Giebe, of the Reichsanstalt, visited the National Physical Laboratory in order to make an inter-comparison of various standards. The paraffin wax was dissolved off the standard inductance and the coils remeasured. Some slight variations from the original dimensions were observed, and the value of the mutual inductance coefficient when recalculated was found to be 10017·78 microhenries. The coils were not rewaxed.

In 1913 a similar standard, ordered by the Japanese Government, was under construction by Mr. R. W. Paul. This was sent to the Laboratory to be wound and measured with the view of the calculation of its coefficient. The work was delayed by the War, and in 1920 the grooves to hold the wire were recut in the Engineering Department and the standard completed and sent to Japan. It had only just arrived when it was destroyed by the earthquake of 1923. Soon afterwards the Japanese Government placed an order for a new standard. It was then suggested, and the suggestion was welcomed by the Lord President of the Council, Lord Balfour, that the new standard should be constructed at the National Physical Laboratory, and presented by the Lord President to the Japanese Government as a token of sympathy for the losses sustained by the earthquake; this standard is the scientific gift referred to in the *Times* notice.

COMPARISON OF NEW JAPANESE STANDARD WITH NATIONAL PHYSICAL LABORATORY STANDARD.

Temp. Jap. Standard.	M_J Calculated.	$M_{N.P.L.} - M_J$ Observed.	$M_{N.P.L.}$ by Difference.	Temp. N.P.L. Stan.	$M_{N.P.L.}$ at 15°.	Deviation from Mean.
	μH.	μH.	μH.		μH.	μH.
15·6	10010·03	7·81	10017·84	15·2	10017·84	0·02
15·0	10010·02	7·86	10017·88	14·3	10017·90	0·04
15·5	10010·03	7·84	10017·87	15·0	10017·87	0·01
15·0	10010·02	7·79	10017·81	14·2	10017·84	0·02
16·2	10010·04	7·83	10017·87	15·4	10017·86	0·00
16·2	10010·04	7·86	10017·90	15·9	10017·87	0·01

Mean Value of N.P.L. Standard at 15° C., 10017·86 μH.

A full description of the standard will appear shortly in the Collected Researches of the N.P.L. in a paper by Messrs. Dye and Hartshorn of the Electricity Department of the Laboratory. Fig. 1 is a reproduction of a photograph of the standard. The interest for physicists, however, lies in the fact that its construction has enabled a very careful comparison to be made of the values of the N.P.L. standard since 1914. The recent results are given in the accompanying table taken from the paper in which the method of comparison is described.

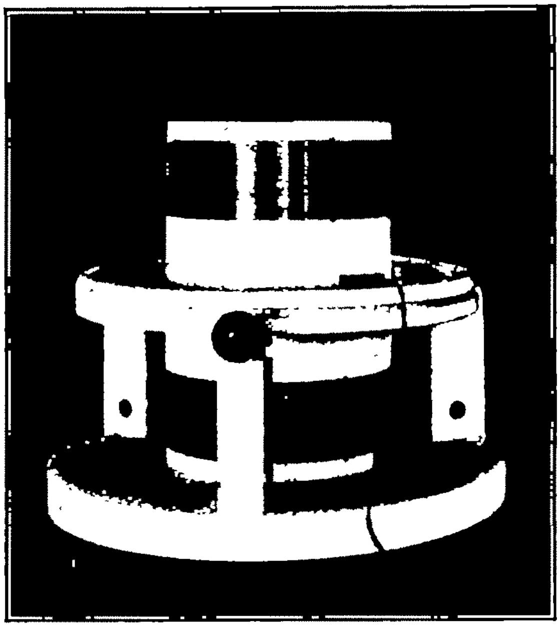

FIG. 1.—Photograph of the Japanese standard mutual inductance, consisting of the inner marble cylinder upon which are the upper and lower single layer primary windings and the outer ring-shaped secondary winding in the channel turned in the ring. The ring is supported on levelling and centring screws attached to the three marble pillars fixed to the base.

It thus appears that the value of the N.P.L. standard in terms of the new Japanese standard of 1927 is 10017·86 microhenries. In 1921 its value was found by Dr. Dye by comparison with the first Japanese standard to be 10017·83 microhenries. As already stated, its calculated value found in 1914 was 10017·78 microhenries.

Insulin and Synthalin.

TO elucidate the chemical constitution of a compound of the nature of insulin, two main lines of approach may be followed; methods may be devised for the isolation of the substance in a state of chemical purity, preferably, if possible, in crystalline form, or the problem may be tackled from the opposite direction, by the synthesis of bodies possessing an insulin-like action, one of which may ultimately be found to be identical with insulin itself. In the following account, brief reference is made to certain of the investigations recently carried out with the view of determining the properties and constitution of insulin.

PURIFICATION OF INSULIN: CRYSTALLINE INSULIN.

In a series of publications, Abel and his collaborators have described methods by means of which solutions of insulin may be made to yield crystals of the active principle. The original method was first described by J. J. Abel in the *Proc. Nat. Acad. Sci.*, vol. 12, p. 132; 1926, and involved the use of a purified insulin as a starting-point. To obtain this purified insulin, material of a unitage of about 10-15 units per mgm. was dissolved in weak acetic acid and precipitated by means of pyridine, the whole process being repeated a number of times: by this means, 35-40 per cent. of inactive matter was removed. The material was then extracted in 90 per cent. phenol, the insulin passing into solution, from which it was precipitated by the addition of a large excess of water. The pyridine precipitation in acetic acid solution was then repeated several times, but with a sodium chloride precipitation between the first and second pyridine treatment. The material thus obtained contained 40 units or more per mgm., and was used as the starting-point for preparing crystalline insulin (J. J. Abel and E. M. K. Geiling, *Jour. Pharmacol. and Exper. Therap.*, vol. 25, p. 423; 1925).

To a solution of the purified material in acetic acid was added an acidified solution of brucine, by means of which impurities were precipitated. By the addition of pyridine to the clear solution of insulin, the compound was precipitated, largely in a crystalline form, and could be recrystallised by the same means or by dissolving in disodium hydrogen phosphate, adding acetic acid to slight permanent turbidity and setting aside for crystallisation to take place. The crystals obtained were doubly refracting, and belonged to the rhombohedral division of the hexagonal system.

More recently Abel and his collaborators have described a simpler method of obtaining crystals (J. J. Abel, E. M. K. Geiling, C. A. Rouiller, F. K. Bell, and O. Wintersteiner, *Jour. Pharmacol. and Exper. Therap.*, vol. 31, p. 65; 1927). The brucine method was applied directly to material of a unitage of 13 per mgm., and the use of the tedious phenol purification was found to be unnecessary. The material now used gave only a slight precipitate on the addition of the acidified brucine solution, but the addition of pyridine brought down the impurities, together with some of the insulin, provided the reaction was kept well to the acid side of the isoelectric point of the latter. The addition of ammonia to the clear filtrate now brought down crystals, or more usually, they appeared on setting aside to crystallise. The crystals were either rhombohedral and doubly refractive or rhombic dodecahedrons. Tested against the international standard of insulin, the crystalline material showed a unitage of 40 per mgm., and the activity was unchanged on recrystallisation.

Before discussing the chemical properties of the purified material, reference may be made to the work of Dodds and his collaborators (F. Dickens, E. C. Dodds, W. Lawson, and N. F. Maclagan, *Biochem. Jour.*, vol. 21, p. 560; 1927). By entirely different methods from those used by Abel, these workers have succeeded in obtaining an insulin of a unitage of about sixty to the milligram, but they were unable to crystallise their product, using Abel's first method. The steps in the purification were as follows: the insulin, in aqueous solution, was precipitated by the addition of trichloracetic acid to 2 per cent., leaving some of the impurities in solution. The precipitate was dissolved in dilute hydrochloric acid and the potency again precipitated, this time by means of one-third saturation with sodium chloride. The precipitate was again dissolved, in slightly acid water at pH 4·0, and an oxalate-oxalic acid mixture of similar reaction added. After standing, the precipitate was centrifuged off, re-dissolved in dilute acid, precipitated as the picrate, and regenerated as the hydrochloride by Dudley's process, which consists in precipitating the hydrochloride from an alcoholic hydrochloric acid solution of the picrate by means of acetone. The purest material was prepared by the use of five oxalate precipitations.

Examination of the chemical properties of the products obtained by these two groups of workers shows that they are of protein nature, thus confirming the conclusions of other investigators. The biuret, Millon's, Pauly's and ninhydrin tests are positive and the tests for tryptophane negative: Molisch's test is also negative. The nitrogen content is about 15 per cent. or somewhat less. Abel suggests the formula $C_{45}H_{69}O_{14}N_{11}S$. Dodds finds that the arginine, histidine, and especially the lysine fractions are lower in the more purified specimens of his material. The results obtained agree in general with those published by other workers, although there are discrepancies as regards the percentages of the various fractions found on hydrolysis, and in some cases also as to the presence or absence of a particular amino-acid.

Abel has raised the question as to the relationship between the sulphur of the molecule and the physiological activity. He found that boiling the insulin with $N/10$ sodium carbonate for a short time resulted in loss of potency together with a change in the condition of a portion of the sulphur, such that subsequent treatment with dilute acid led to the liberation of hydrogen sulphide. His experiments suggested that the amount of this 'labile' sulphur present was directly proportional to the potency of the particular sample under examination, the proportion of both total and 'labile' sulphur increasing with increase in potency. About one-third of the sulphur of the molecule appears to be liberated by the dilute alkali in the case of the crystalline preparation. Dodds, however, states that there is no relationship between the sulphur content and the physiological activity, the former being the same in the purest as in relatively impure material. Whether the sulphur in the molecule plays a dominant rôle in relation to the physiological activity, must, then, be left to future work to decide.

The investigations into the chemistry of insulin appear to indicate that it is either itself of the nature of a protein or, as extracted from the pancreas, is always associated with protein material. The fact that products of varying physiological activity can be obtained seems to suggest that the insulin molecule is of a simpler nature than that of any of the compounds hitherto prepared, but is associated with protein material of varying amount and composition, depending upon the particular processes of extraction and purification adopted.

SYNTHALIN.

The synthesis of certain compounds with an insulin-like action has been described by Frank, Nothmann, and Wagner, one of which, 'synthalin,' has been subjected to extensive clinical trial in cases of diabetes mellitus. The starting-point of this work was the well-known observation that guanidine and its compounds produce, on injection into animals, symptoms resembling tetany in human beings, and even convulsions. The authors found that a dose of 0·3 gm. per kgm. body weight, injected subcutaneously into a fasting rabbit, produces convulsions, accompanied by a fall in the blood sugar to 0·035-0·05 per cent. (E. Frank, *Naturwissenschaften*, vol. 15, p. 213; 1927): the administration of sugar or adrenalin can postpone the onset of the hypoglycæmia, given with the guanidine; but once the convulsions have commenced, sugar cannot relieve them. Smaller doses producing no symptoms also cause no fall in blood sugar. Methyl and dimethylguanidine produce convulsions independently of the blood sugar level: the authors therefore turned to a different type of guanidine compound, namely, agmatine, which was first extracted from herring-sperm by Kossel, but can now be prepared synthetically by a process devised by Heyn. Agmatine is amino-butylene-guanidine, and has the formula

$$HN=C\begin{cases}NH_2\\NH\,.\,CH_2\,.\,CH_2\,.\,CH_2\,.\,CH_2NH_2.\end{cases}$$

In doses of 0·08 to 0·1 gm. per kgm. body-weight, this compound produces a fall in the blood-sugar of 30 per cent. without any obnoxious symptoms: larger doses cause a primary hyperglycæmia, followed by a fall in the blood-sugar and convulsions. The next higher homologue of agmatine, amino-pentyleneguanidine, has a more powerful hypoglycæmic action than the former compound: 0·2 gm. per kgm. body-weight is a convulsive dose, and the symptoms are similar to those produced by insulin, which was not the case with the other compounds investigated. Further, both substances resemble insulin in that the symptoms can be relieved by administering glucose.

Synthalin is closely related to the last two guanidine derivatives, being a diguanidyl derivative of a long chain aliphatic hydrocarbon, but the exact constitution has not yet been published. The toxic effects have been still further dissociated from the hypoglycæmic, doses as low as 0·003 gm. per kgm. body-weight producing a definite decrease in the blood-sugar. In applying these results to cases of human diabetes, Frank found that 20-25 mgm. constituted a suitable dose, and that up to 150 mgm. could be given in the course of four days. Such a dosage resulted in the utilisation of 40-50 gm. of glucose, which would otherwise have been excreted in the urine. If 125 mgm. cause the utilisation of 160 gm. of glucose in four days, 1 mgm. is equivalent to 1·24 gm. glucose, or, roughly, to one unit of insulin. Weight for weight, synthalin is therefore considerably less potent in causing a fall in the blood-sugar than the best samples of insulin.

The use of synthalin has in its favour the facts that it can exert its action after oral administration, and that this action, although slower in onset than that of insulin, is much more prolonged: to its disadvantage is the fact that unpleasant symptoms may be produced by it in many patients. The probable mode of action of the drug throws some light on the origin of these symptoms. Workers at the National Institute for Medical Research in London have found that synthalin only produces a decided fall in the blood-sugar in the normal animal in doses which also exert a definitely toxic action on the liver (*Lancet*, vol. 2, p. 517; 1927). This effect on the liver presumably results in a depression of the new formation of glucose which occurs in that organ, and also explains in part the unpleasant symptoms of nausea, anorexia, etc., frequently encountered in patients taking the drug: these symptoms have been found by Continental observers to be mitigated by the administration of a bile salt derivative, sodium dehydrocholate, to stimulate bile secretion, during the period of action of the synthalin: the toxic effect of the latter on the liver is believed to be counteracted by the simultaneous increase in the activity of the organ.

Apart from its action on the liver, synthalin also accelerates the disappearance of glucose from the circulation in the eviscerated spinal preparation, although the sugar vanishing is not laid down as glycogen in the muscles as is the case with insulin: moreover, large toxic doses of synthalin are necessary to demonstrate this effect. It therefore appears that the two main actions of insulin, depression of new formation of glucose in the liver and accelerated metabolism of sugar present in the blood, are represented in the effect of synthalin, but the fate of the sugar disappearing, which, in the case of insulin action, is partly laid down in the muscles as glycogen and partly burnt to carbon dioxide and water, is not absolutely similar in the two cases.

The clinical usefulness of the compound appears then to depend on how far its insulin-like action can be dissociated from its toxic effects: and this seems to occur to a different degree in different people. In Great Britain, the Medical Research Council has set on foot clinical investigations in a number of different centres, preliminary reports of which have recently been published (*Lancet*, vol. 2, p. 517; 1927): the same journal also contains a paper by E. G. B. Calvert on the treatment of diabetes by the drug (*ibid.*, p. 649). The results of these investigations show conclusively that synthalin is not a complete substitute for insulin. In certain patients, roughly one-third of the cases so far treated, it exerts a definitely toxic effect, the symptoms suggesting intestinal irritation, although a hepatic element may also be present. In a certain number it appears to be without action, but in others it enables the dosage of insulin to be reduced, although very rarely can its use be abandoned altogether. It has more effect in reducing the glycosuria than in reducing the blood-sugar.

The difficulties of estimating the value of synthalin, or that of any similar therapeutic agent, are considerable: thus, in a case in which synthalin has exerted a favourable influence, the patient may remain well, after withdrawal of the drug, on simple dieting alone; or if symptoms of gastro-intestinal irritation supervene, the accompanying loss of appetite, by reducing the food intake, may suffice to reduce the glycosuria and ameliorate some of the symptoms of the disease. Finally, since synthalin has a toxic action on the liver, it is possible that apparently good results may be due to a mild degree of this toxic action, in which case only time can disclose its real value even in the cases which appear to react successfully to it at the present moment.

Synthalin, then, is not a substitute for insulin: its real usefulness lies rather in the encouragement its discovery brings to the further investigation of synthetic compounds having an insulin-like action.

The Control of Plant Diseases.

"*Be ye ashamed, oh ye husbandmen; howl, oh ye vinedressers, for the wheat and for the barley; because the harvest of the field is perished. I have smitten you with blasting and mildew.*"—Joel i. 11 and Amos iv. 9.

In opening the discussion between Sections K and M on the control of plant diseases, at the Leeds meeting of the British Association, Mrs. N. L. Alcock chose the above text, and passing lightly over the superstitions of the past regarding disease, she turned to the problem of control as seen to-day by the pathologist and agriculturalist. From the practical point of view, the first full recognition of the importance of plant diseases came with the epidemic of American gooseberry mildew. In 1905, Prof. Salmon, of Wye Agricultural College, while Ireland alone of the British Isles was definitely affected by the disease, gave a clear warning of the need of legislative control of both American gooseberry mildew and of potato wart disease. In another direction the warning was spread in 1909 by Prof. Sommerville in his references to the white pine blister rust, *Cronartium ribicola*, which he stated was still unknown in America, though it was to be feared that the day was not far distant when its footing in North America would be secured. To-day the losses in America due to this disease are credibly reckoned as enormous.

Neither the spread of American gooseberry mildew in Britain, however, nor the ravages in American forests by pine blister rust, served to awaken fully the British people to the need of strict control. The full awakening came with the spread of wart disease, which, though described as a new malady of the potato in England by Prof. Potter and Mr. Massee in 1902, was not recognised as a menace to our food supplies until some years later. Happily, the lesson had been partly learned from the spread and havoc of mildew and blister rust, and legislation was initiated, at first haltingly, in an effort to devise rules for disease control, and later, as experience widened, amendments followed and mildew was lessened generally. The credit for the decline of mildew may be given to legislation; but it must not be forgotten that as in human infectious diseases, so also in plant diseases, there is probably an ebb and flow, not yet fully understood.

At first little was heard of wart disease, though a further warning of the dangers which it created was given by Prof. Salmon, but its spread led in 1907 to the Destructive Insects and Diseases Act, which may be considered the first important step in legislation for the control of plant diseases, and served to bring the subject of control into prominence. The establishment of inspectors to administer the control, and of mycologists and entomologists to recognise and to teach others to recognise plant pests, followed naturally.

In 1909 a further landmark was reached with the discovery that certain varieties of potato were immune to wart disease. With the work on this discovery the names of Mr. Gough and Mr. Snell will always be associated. Little is yet known as to the nature or degree of permanence of this immunity, but so far the latter has generally been maintained. Here geneticists have helped greatly, since there is cause for the belief that immunity may be a Mendelian character which, through breeding, may yield increasing crops of disease-resisting plants. But in this field of research there is still much to do before our crops are immune to disease, mature quickly, are hardy and produce acceptable fruit in abundance, and until the possibilities of success on these lines are assured, effort must be centred largely on the control of existing disease. At the present moment the English Phytopathological Service consists of three sections—official, inspectorate, and advisory respectively—and comprises entomologists, mycologists, an administrative unit forming part of the Horticultural Division of the Ministry of Agriculture, the Ministry's inspectorate—all members of which have received training in pathology—a corps of advisers—consisting of an entomologist and a mycologist in each agricultural province—and research workers on both entomology and mycology, who are stationed at Rothamsted Experimental Station, Long Ashton Fruit Station, Bristol, the Imperial College of Science, London, the Fruit Station at East Malling, the Lee Valley Station, Cheshunt, the London School of Tropical Medicine, and other institutions.

For the full effectiveness of such a service the convinced and willing co-operation of the grower is an essential factor, for not only must the grower play his part in an advisory council, but he must also take his part in the framing and enactment of agricultural legislation. The business value of measures of control must never be forgotten. The knowledge of those who are to administer control must be accurate and wide, and above all practical. Thus, for example, in some parts of Scotland the spraying of gooseberries against American gooseberry mildew with washing soda is cheap and effective; in other parts of Scotland such spraying is harmful and destroys all hope of a crop. The use of weights and measures familiar to the grower, the need of clear and simple language in the exposition of the facts of the grower's problems, and moderation in policy in the framing of rules and regulations for the guidance of the grower, are vital to the successful co-operation of the administrative body and the producer.

There is to-day great need of a full investigation of common seed-borne diseases; for wheat may bear bunt spores, flax-seed may carry the resting mycelium of *Colletotrichum linicolum*, and both the pycnidia of *Phoma betæ* and the sori of the rust *Uromyces betæ* may be transmitted by the seed of the sugar-beet. At least some seventy common diseases are thus carried. On this aspect of control there is much need for chemical research with the view of the elimination of disease before the seed is sown.

It may be considered fortunate that Great Britain has not yet been faced by a disastrous plant-disease epidemic, but in America the loss by wheat-rust alone is reckoned at not less than 100,000,000 dollars. Nevertheless, the constant and steady toll taken from our food resources is formidable and must amount annually to tens of thousands of pounds. It may, however, be held that the greatest available field for the exercise of control of disease lies in horticulture, for here the margin of profit is relatively broad, labour is adequate, there is no lack of interest on the part of the grower, and much good can be done. Here also is wide scope for the exercise of plant sanitation, for clean cultivation, the destruction of diseased plants, the removal of weeds and moribund tissues, and the destruction of refuse by fire. The incidence of disease may also be lessened by careful selection of site, while much may be gained by closer co-operation between growers and the staffs of our botanic gardens. Both for horticulture and forestry the importance of nurseries calls for fuller recognition, for while in horticulture many diseases may be fought with reasonable hope of success in adult plants, to avoid disease in the nursery is better than to control it in later life. With forestry the matter of nursery control is more urgent, for in many cases there is little hope of disease control other than by the elimination of the cause in the nursery itself.

Dr. W. B. Brierley, who spoke from the point of view of agriculture, dealt at length with the training and supply of workers, the financing and staffing of laboratories, and the field and administrative services for research on disease control, and strongly urged the need for careful gradation from pure to applied research, without which the full integration of investigation could not be realised. In urging the claim for extended research foundations in our universities and for crop stations, he held that by the enlargement of such foundations and stations the work of control could now be best advanced. There is still great need for the popularisation of knowledge regarding the nature and dangers of plant diseases, and he held that by oral instruction to the grower, and by the wider use of clear and concise printed matter, disease control would be materially promoted. In his opinion there was, however, a danger that the training of plant pathologists might remain a function of pure botany rather than become one of agriculture, and this he considered a matter for regret and correction.

Miss E. Welsford, who followed, spoke from her experience of the control of the diseases of the clove in Zanzibar, and urged the need for improvements in the methods of cultivation and plant hygiene for all crops. In her experience the practical sides of healthy plant physiology were of greater importance in the battling of disease than cure; for while the latter would ever be essential, the primary duty of the plant pathologist must increasingly become the avoidance of disease by assuring healthy growth for crops as a whole.

Some of the difficulties in control were referred to by Sir Daniel Hall, who discussed the breeding of plant varieties immune to disease. In his opinion such breeding must be slow in securing satisfactory results, since the starting-point is immunity to known diseases in a few varieties which may still be prone to, and may be even more prone to, other diseases than they were before immunisation to one. He warned all who must deal with the practice of agriculture that progress in one line of control would not assure immunity for crops as a whole, and that step by step the problem must be probed until a sound knowledge of the effects of environment on immune varieties has been attained. With a widened understanding of the advantages and defects of a known environment for a known crop would come a surer foundation on which all could co-operate in the elimination of disease.

Dr. Malcolm Wilson strengthened the plea of Sir Daniel Hall for the extended study of environment, and while laying emphasis on the need for fuller knowledge of the condition of individual crops at the time of infection, he held that the plant pathologist could best be fitted for the practical work of agriculture relating to the cure of disease by the fullest possible training in both healthy physiology and pathology.

Mr. W. A. Millard discussed the processes of green manuring as preventive of scab on potatoes, and described experiments which threw light on the beneficial effects of such treatment.

Dr. W. G. Smith discussed the differences between the work of the adviser and that of the agricultural inspector, and while admitting that the present system of administration was advanced and enlightened, he urged the need for the fuller study of plant diseases on the spot, for by such study the complications of the problem of disease could often be more fully appreciated and approached than by other means.

Prof. Link spoke of the close parallelism between the problems of disease control in Britain and the United States of America, and stated that the work of control in America was still hampered by the inadequate training of plant pathologists in pure botany. On the other hand, there are other directions in which improvements are indicated, and in particular it must be assured that a closer relation is established between the research worker and the grower. By such a relation the work of both the investigator and the grower would be accelerated.

In conclusion, Mr. Stoughton discussed the methods of propaganda against plant disease, and emphasised the importance of the personal factor for both the investigator and the grower, by which investigation could be stimulated on one hand and knowledge accepted on the other, to the benefit of all concerned and the assurance of unbroken progress.

J. McL. T.

University and Educational Intelligence.

Cambridge.—Prof. A. Hutchinson, professor of mineralogy, has been elected Master of Pembroke College.

Sir Arthur Shipley, late Master of Christ's College, left £5500 to Christ's College for the endowment of a fellowship, along with various other bequests, including some relics of Darwin. As we announced in our issue of Oct. 29, p. 640, parts of his library are going to the Molteno Institute of Parasitology, the Balfour Library, and the Cambridge Philosophical Society.

The Education Committee of the West Riding of Yorkshire announces in its report for 1926–27 a new departure in regard to provision of education for the adolescent: the inauguration at Castleford of a "centre for social and physical training" at an estimated cost of £500. Nine other similar centres are to be established in the course of the years 1927–1930, under the direction of a juvenile organisations committee, representative of all the local organisations engaged in social work amongst the young. Fifty-one scholarships tenable in universities were awarded in 1926–27, the average value being £78 a year. The field of selection of candidates (now 250 annually) has been widened by the grant of 'continuation' scholarships covering tuition, travelling, and maintenance expenses of preparation for the Higher School Certificate examination. Eighty per cent. of the pupils above sixteen are scholarship holders. Secondary school entrance scholarships were awarded to 2030 out of 5·5 times that number of candidates. Technical exhibitions numbered 3291.

The Rockefeller Foundation has issued another, the eighth, series of "Methods and Problems of Medical Education." Of the 37 articles in this series, 7 deal with British practice and institutions. Sir Lenthal Cheatle discusses "English Surgery: Practice, Teaching, and Research," and Sir Archibald Garrod the "Teaching of Clinical Medicine in England." The medical and surgical 'units' of St. Bartholomew's Hospital are described by Prof. Fraser and Prof. Gask respectively. Details are given of the Electrocardiograph Department, Edinburgh Royal Infirmary, by Dr. W. T. Ritchie, and of the Department of Surgery, University of Edinburgh, by Prof. Wilkie. The new obstetric hospital, University College Hospital, is described by Sir George Blacker and Prof. Browne. The remaining articles mostly deal with special medical departments of institutions in America and Europe, including a useful one on medical postgraduate work in Germany, by Prof. Curt Adam. The volume is profusely illustrated with photographs and plans and contains useful information on staffing and finance.

The appointments to Ramsay fellowships in chemical science for this session, British, Dominion, and foreign, are practically completed. At the present time ten fellowships are being held in the universities and colleges of Great Britain. The list of awards for the present session is as follows, the institution selected by the fellow for his research being given: *British Fellowships*: Dr. R. F. Hunter, Imperial College of Science and Technology, London; Mr. A. M. Taylor, University of Cambridge; *Glasgow Fellowship*: Mr. James D. Fulton, University of Manchester; *Canadian Fellowship*: Dr. W. H. Barnes, Royal Institution, London; *Danish Fellowship*: Miss Augusta M. Unmack, University of Oxford; *French Fellowship*: M. Robert le Guyon, University College, London; *Italian Fellowship*: Dr. Gastone Guzzoni, Royal School of Mines, London; *Japanese Fellowship*: Dr. Yohei Yamaguchi, University College, London; *Spanish Fellowship*: Senor Fernando Calvet, University of Oxford; *Swedish Fellowship*: Mr. H. Liander, University College, London. The total value of the annual amount of the fellowships that is awarded is approximately £4000, of which about £3000 is provided by grants from Dominion and foreign sources.

Calendar of Customs and Festivals.

February 1.

St. Bridget.—Next to St. Patrick the most important of the Irish saints, the patroness of arts and culture. She, with seven virgin companions, the first nuns in Ireland, founded a church which stood under an ancient oak on what is now the site of the city of Kildare. The popularity of the saint, as indicated by the frequent use of Bridget as a Christian name, together with the survival of many pagan elements in relation to her, point to the pre-existence of a widely diffused and important cult. Her shrines are frequently associated with oak or ash groves, and she herself is connected with fire. This is shown by the story told by Giraldus Cambrensis of an ashless undying fire sacred to her, which was tended by twenty virgins in an enclosure taboo to men, as well by other of her attributes.

Popular custom points to a connexion of St. Bridget with fertility. On Jan. 31, the eve of her feast, it was the custom in the Isle of Man to cut green rushes and, standing at the door, to invite the saint to enter as the rushes were strewn on the floor to make a bed or carpet. The meaning of this practice is made clearer in the Western Isles of Scotland, where on the night of Feb. 1 a sheaf of oats was dressed in woman's clothes by the mistress and her maids, and placed in a basket with a stick beside it while saying, "Bri'id is come, Bri'id is welcome." In the morning, if the mark of the stick was found in the ashes, it portended a prosperous year. The custom of making rush crosses in honour of St. Bridget in association with a more or less solemn feast, widespread in Ireland, has suggested a connexion with sun-worship.

Like St. Agnes, St. Bridget, a virgin saint, has come to be associated with fertility by a process of synthesis. Her cult has absorbed that of the pagan goddess Brigid, goddess of fertility, of fire and of the arts of civilisation, who is identified with the goddess Dann (Welsh Dón) of the Tuatha de Danaan. She was the most important of the Celtic goddesses and belongs to that stage of Celtic religion when goddesses were more important than gods. In Gaul, Cæsar equates her with Minerva. In Britain she was the eponymous goddess of the Brigantes. One of her shrines was situated at Bath.

February 2.

Candlemas.—"The Purification of the Virgin Mary," also called "Christ's Presentation" and the "Holiday of St. Simeon." It is also known in the north of England as the "Wives' Feast."

The ceremony of purification after childbirth, perpetuated in the modern 'churching of women,' now, of course, a service of thanksgiving, is a necessary accompaniment of the idea of taboo involved in the great crises of life, such as birth and death, in primitive thought. Among most primitive peoples, women after childbirth are regarded as unclean and dangerous, and as such are subject to certain prohibitions. In Korea, for example, they must veil themselves from the sun for a period of varying length according to their rank. The uncleanness may be removed by various means; in the New Hebrides by washing in new coconut milk or by stroking the limbs with branches which remove the pollution. In the Malay Peninsula mother and child are laid on a platform under which a brisk fire is lit, sometimes with fatal results.

The Church celebrated the feast by a solemn procession, in which candles were borne in procession. According to some authorities, all candles for use during the year should have been blessed on that day. The observance was continued in England up to the Reformation and was forbidden by statute in the reign of Edward VI.

The custom and name have been derived from Simeon's naming of Christ as "the Light of the World"; but ecclesiastical tradition is probably nearer the truth when it states that the ceremony was instituted because the pagans on that day carried lighted candles in honour of Pluto and Proserpine or, according to another account, Mars and his mother Februa—a function of Juno as presiding over the purification of women. In order to divert the Christian from these pagan practices, it was enjoined on all to carry candles in honour of the Virgin and Christ. The feast therefore perpetuated the cult of male and female chthonic or fertility deities and was connected with the purification of women. It is significant that in Britain St. Bridget has come to be associated with Candlemas.

In popular lore "on Candlemas Day throw candle and candle-stick away," said to mean that the use of tapers at Vespers and Litanies which had continued through winter, now ceased until All Hallow Mass. It certainly marks a period in a tradition older than the ecclesiastical. On Candlemas Eve the Yule brand was kindled and allowed to burn until sunset, when it was quenched and set aside to light the Yule log in the next season. The distinctively Christmas decorative foliage, the rosemary, bay, ivy, holly, and mistletoe were taken down and replaced by the box. In the Scottish Highlands St. Bridget's Day (Feb. 1, O.S.) was the first day of spring. It was the custom in Scotland for school children to make a present to the schoolmaster on Candlemas Day, the boy and girl giving the most becoming king and queen with certain privileges, such as asking for a weekly half-holiday and the remission of punishments over a certain period. It was also customary in some towns for a football match to be played. Both customs are significant in this connexion.

February 3.

St. Blaise.—Bishop and Martyr, born at Sebaste, Armenia, martyred by Agricola, A.D. 316. His legend records his fondness for and control over animals. At his command a wolf gave up a pig stolen from a poor woman. The woman brought the head and feet and a candle made of the pig's fat to the saint when he was in prison. Hence the custom of burning a candle to him for the animals of the household. He healed a youth dying through having swallowed a bone. Anyone in a similar state invoking the saint and commanding the bone to pass down or up in his name would be healed. Several Christian women were martyred with St. Blaise. When ordered to sacrifice to the heathen gods, they asked to be allowed to wash the idols that their offering might be the purer; but they threw them into the lake. This suggests a customary ritual, otherwise consent would scarcely have been given so readily.

St. Blaise was tortured with a sharp comb like that of the wool-comber, and is credited with having invented wool-combing. He was, therefore, the principal figure in the procession of the wool-combers of Bradford, which took place on this day, Jason with the Golden Fleece being the next in importance. By folk etymology he is associated with a custom whereby country women making a holiday on his festival burnt the flax and distaff of any woman found working, and also with the hill-top fires it was customary to light in some parts of the country on this date.

Societies and Academies.

LONDON.

Royal Society, Jan. 19.—**E. S. Horning** and **A. H. K. Petrie**: Enzymatic function of mitochondria in the germination of cereals. In the resting stage of maize, wheat, and barley, mitochondria occur in the scutellum and endosperm. During germination they become numerous in the scutellum, and are secreted in large numbers from epithelial cells into adjacent starch-containing cells of endosperm. These secreted mitochondria aggregate round starch grains prior to their corrosion; as corrosion commences the associated mitochondria seem to disappear. Throughout the period of endosperm depletion, mitochondria are thus secreted and migrate through the emptied cells to the zone of active hydrolysis, where they become associated with the starch grains. In isolated endosperms, mitochondria of intracellular origin effect starch hydrolysis and depletion at a slower rate corresponding to their lesser numbers. There is no evidence for secretion of mitochondria from the aleurone layer or of depletion being affected by secretion of an enzyme therefrom.

S. Dickinson: Experiments on the physiology and genetics of the smut fungi. No infection of oat or barley seedlings by pure cultures of smut fungi occurs when one gender (sex) is present; but when two genders are present, 90 per cent. infection is obtained.

P. H. H. Gray: Formation of indigotin from indol by soil bacteria. Oxidation of indol to indigotin can be effected by bacteria. Two new species have been isolated from soil. *Pseudomonas indoloxidans* oxidises in solution cultures and on agar media; *Mycobacterium globerulum* produces very small amounts, on agar media only. A new species of Micrococcus can also produce crystals on indol agar. Indol does not act as a source of energy; of the carbon compounds tested, glycerol appears most readily to act as energy-source to the oxidation. Bacterial numbers and amount of indigotin produced increase with higher ratios of carbon to nitrogen. Indol is oxidised only by young growing cultures, and can be oxidised in the absence of other nitrogen compounds; it depresses multiplication of bacteria.

R. A. Fisher: Triplet children in Great Britain and Ireland. Results of measurements, and of genealogical inquiries on three years' data from recipients of the Royal Bounty, are given. Six physical measurements taken on 117 children show correlation between pairs of unlike sex conformable with that obtained by the author from Lauterbach's measurements on twins, and with that between adult brothers and sisters. Pairs of like sex are more highly correlated, the results being well fitted by the supposition that about 54 per cent. of the surviving like-sex pairs are monozygotic in origin, and that these have a correlation 0·94. Relationship data confirm paternal influence, and sex distribution of related twins strongly suggests that this is confined to causation of di-embryony. If maternal influence conditions both dizygotism and di-embryony, the slightly higher values obtained from these and other data for maternal influence indicate that di-embryony is the more strongly inherited phenomenon.

J. W. H. Harrison: A further induction of melanism in the lepidopterous insect, *Selenia bilunaria* Esp. and its inheritance. By administering food containing manganese chloride to a strain of *Selenia bilunaria*, known by the use of adequate controls to be free from heritable melanism, melanic insects have been developed. This melanism is inherited as a Mendelian recessive. Certain mosaics were obtained in the critical treated brood, but these, from experimental tests, seem to represent cases of somatic induction, the germ plasm being apparently unaffected. The effect is not of the Lamarckian type, but rather illustrates a new evolutionary principle, that heritable variations may be induced by means of the food supplied. The metal seems to be the active agent.

J. W. H. Harrison: Induced changes in the pigmentation of the pupæ of the butterfly, *Pieris napi* L. and their inheritance. The pupæ of *Pieris napi*, when developed from larvæ exposed at the critical time to lights of different colours, are influenced in their pigmentation, like those of their congeners *Pieris brassicæ* and *P. rapæ*. As Dürken and Brecher found in the case of *P. brassicæ*, the green pupal colour, acquired under the influence of orange light, is inherited.

F. G. Gregory: The differential effect of the ions of three-salt solutions on the growth of potato plants in sand culture. A method of statistical analysis is developed enabling assessment of the effect of single ions on growth of plants in culture solution consisting of a mixture of salts, and has been applied to data published by E. S. Johnston. The kations in the solution have for each relative ionic concentration (ionic proportion) a greater effect than any of the anions used.

Sir Kenneth Goadby: Bacterial proteins: presence of alcohol-soluble proteins in bacteria. By a method, shown to produce minimum change on protein constituents, an alcohol-soluble protein, having many of the characters of the similar proteins of cereal seeds, has been extracted from Streptococci, Staphylococci, *Bacilli Hoffmann*, *typhosus*, *coli com.*, *paracoloides*, and *Micrococcus catarrhalis*. The Molisch-reacting substance seems to form an important constituent of bacterial structure.

F. W. R. Brambell: Development and morphology of the gonads of the mouse. (Part 2.) The paper deals with 64 animals irradiated during pregnancy or lactation. Degenerative changes in corpora lutea start at the same age in the sterile as in the normal ovary. They proceed slowly, and the old corpora lutea become practically permanent components of the sterile ovary. This is attributed to absence of competition with maturing follicles and new corpora lutea.

R. C. Punnett: Linkage groups and chromosome number in Lathyrus. A fundamental requirement of the chromosome heredity-theory is that the number of linkage groups and characters showing independent assortment in a species should not exceed the haploid number of chromosomes. This holds good for the only species—Drosophila—hitherto tested adequately. Experiments over twenty years and involving 19 characters have shown that in a plant also (*Lathyrus odoratus*) the number of linkage groups and characters showing independent assortment is 7, the same as the haploid number of chromosomes in this species.

S. Ochoa: Action of guanidins on the melanophores of the skin of *Rana temporaria*. The guanidin hydrochlorides cause contraction of skin melanophores in frogs. This is a direct action, either on the melanophores or the nerve endings in them. Calcium salts antagonise the effect, as they do many of the other effects. It is probable that Collip's parathyroid hormone also antagonises the action of guanidins.

E. J. Maskell: Experimental researches on vegetable assimilation and respiration. (Parts 17 and 18.) In cherry-laurel leaves, at limiting concentrations but under *constant* lighting, there is marked diurnal rhythm of apparent assimilation, falling to very low values at night and rising in morning. At any point in the diurnal march, assimilation can be increased by increasing carbon dioxide up to the limit set by the light-intensity used. Diurnal rhythm of assimilation is due to a rhythm of stomatal opening. At small opening, assimilation rate is approximately proportional to porometer rate; as the stomata open and the porometer rate increases, the assimilation rate approaches asymptotically to a level determined by non-stomatal resistances in the diffusion path of the carbon dioxide.

PARIS.

Academy of Sciences, Dec. 19.—**A. Lacroix**: The hyperalkaline quartziferous rhyolites and trachytes, with reference to those of Korea.—**P. Villard**: The law of absorption of the X-rays by matter. The total absorption coefficient is regarded as the sum of two terms, a diffusion coefficient taken as independent of the wave-length and the true absorption coefficient, $C\lambda^3$ (Bragg and Pierce). C is considered as a function of the wave-length $C_0\phi(\lambda)$, and from a study of the experimental curve $C=C_0\phi(\lambda)$ it is recognised as a Bjerknes resonance curve, and a formula is developed based on this view. The calculated and experimental figures for zinc are compared.—**Gabriel Bertrand** and **Jules Labarre**: The acetolysis of mannocellulose. The preparation of new sugars, tetramannoholoside and pentamannoholoside. These sugars were produced by the controlled acetylation of mannocellulose by a mixture of sulphuric acid and acetic anhydride, the acetates being afterwards saponified by alcoholic potash and the potassium removed as perchlorate. Details of their chemical and physical properties are given.—**E. Mathias**: Magnetic measurements in the Hautes-Pyrénées, Gers, and Haute-Garonne.—Sir Ernest Rutherford was elected a foreign associate in the place of the late C. Walcott, and Joseph Auclair, *correspondant* for the section of mechanics in succession to Torres Quevedo, elected foreign associate.—**André Weil**: Arithmetic on an algebraic curve.—**Paul Mentré**: The projective displacements of two plane pencils with a common right line.—**Lainé**: The equations $s=f(x, y, z, p, q)$ which are of the first class.—**Paul Flamant**: The development of a linear transmutation in series of powers of the finite differentiation.—**J. Favard**: The normal meromorph functions of the group of translations.—**Henri Milloux**: The theory of integral functions of finite order.—**Georges Valiron**: Some properties of integral functions.—**A. Véronnet**: The evolution of the figures of equilibrium of a heterogeneous fluid mass. The impossibility of a breaking up.—**Belzecki**: A case of critical velocities in the movements of a locomotive on rails.—**G. Rougier**: Observations of the third satellite of Jupiter. A drawing of the spot on the third satellite, previously seen by Antoniadi, is given. From observations of this spot it is concluded that the period of rotation of the satellite equals its time of revolution round Jupiter.—**A. Levêque**: An attempt at an approximate theory of the transmission of heat by convection in a circular cylindrical tube through which is flowing a real fluid in turbulent motion.—**Cordonnier** and **Guinchant**: Inductive capacity in the gaseous state. The results of measurements of thirty-three gases and vapours are given, and their relationship with the refractive indices and chemical constitution discussed.—**Rouelle**: The demultiplier of ferromagnetic frequency.—**Georges Déjardin**: Spectra of phosphorus for different degrees of ionisation. The study of the variations observed in the electrodeless discharge leads to the separation of the spectra characteristic of the different degrees of ionisation of the phosphorus atom. The whole of the results obtained may serve as a starting-point for the development of the classification outlined by Millikan and Bowen. The presence in the photographs of a large number of new lines shows that the spectrum of phosphorus is still imperfectly known, particularly in the ultra-violet, below 2700 A.—**Georges Simon**: Superposition fringes between two half-silvered plates formed by media of different refractive indices:—**Pierre Leroux**: Study of the pleochroism of tourmaline.—**E. Brylinski**: The velocity of the earth. The author holds that the results obtained by A. Piccard and E. Stahel on the Rigi in September 1927, do not disprove Miller's results.—**Edmond Bayle**, **Henri George**, **Augustin Mache**: The identification of works of art. The finger-print of the artist placed on some part of the work has been proposed as a remedy against a forged signature on pictures and other works of art; but it is pointed out that this would be insufficient, since the finger-print could be copied by photomechanical methods. The method suggested as more trustworthy is a combination of photography and radiography.—**A. Dauvillier**: An X-ray tube with an effective wave-length of 8 Angström units. The important feature of the tube proposed, a detailed description of which is given, is a window of very thin cellophane, 0·02 mm. thick, 20 sq. cm. surface, with a support of metallic gauze.—**Henri Belliot**: An attempt at the interpretation of the phenomena of photographic inversion and solarisation.—**W. H. Keesom** and **M. Wolfke**: Two different liquid states of helium. In a series of measurements of the dielectric constant of liquid helium, with diminishing temperatures, at a certain temperature this constant undergoes a sudden change. Earlier observations have given similar indications based on the variation with the temperature of density, specific heat, latent heat of evaporation and surface tension. The change from one state to the other takes place when the pressure of saturated helium vapour is about 38 mm. of mercury.—**B. Bogitch**: Some properties of electrolytic nickel. Measurements of hardness, density, and velocity of solution in hydrochloric acid are given for specimens of nickel of varying degrees of purity. Analyses of the samples are appended: nickel bought as electrolytic is not necessarily pure.—**René Delaplace**: Study of the gas, obtained by cracking oil, for lighting for coast beacons. Analyses of original gas, liquefied gas and residue after rectification of liquid are given.—**I. N. Longinescu**: A new additive property of liquids.—**A. Colani**: Study of the systems uranyl nitrate—alkaline nitrate—water at 25° C.—**R. Locquin** and **R. Heilmann**: The mechanism of the oxidation of the pyrazolines. The basic compounds isolated included the pyrazol corresponding to the pyrazoline oxidised, azines and pyrazoline compounds of the same molecular weight as the azines.—**L. Palfray** and **Mlle. Th. Duboc**: 1, 3, 4, Metaxylenol and some of its derivatives.—**Albert Kirrmann**: The reactions of the α-bromaldehydes. Besides normal aldehyde reactions, other reactions are obtained suggesting an acid bromide. It is shown that with α-bromœnanthol there is no tautomerism, and a probable explanation of the abnormal reactions is suggested.—**W. Ipatief** and **B. Dolgof**: The catalytic hydrogenation of *p*-oxytriphenylcarbinol and *p*-oxydiphenylmethane under pressure. The first step in the reduction of *p*-oxytriphenylcarbinol (catalyst nickel, pressure 80 to 100 atmospheres) is *p*-oxytriphenylmethane and 50 per cent. of this decomposes into phenol and diphenylmethane at 220° C., and pressure 100 atmospheres. The remainder is converted nearly quantitatively into tricyclohexylmethane.—**James Chappuis** and **A. Pignot**:

e compression of town gas. Town gas may contain m 1 to 4 per cent. of oxygen, and at ordinary mospheric pressure this is outside the limit of flammability. Experiments are described showing at mixtures of coal gas and oxygen, compressed to 0 to 200 kgm., are not inflammable if they contain s than 10 per cent. of oxygen.—**R. Lantz** and **A. ahl**: The action of the primary amines on nitroso-naphthol.—**Robert Gibrat**: The focal structure of ectic bodies.—**M. E. Denaeyer** and **Jacques Bourcart**: e chemical composition of the lavas of Ahaggar, ntral Sahara (Jacques Bourcart Expedition, 1922–'23).—**Pierre Bonnet**: The characters of the south anscaucasian geosynclinal.—**Henri Schoeller**: The nbrunais layer and the outside edge of the Briannnais layer, traced from France into Switzerland.—**ul Fallot**: The geology of the region of Antequera ndalusia).—**J. Thoulet**: The double oceanic circulan and the abyssal volcanic columns.—**M.** and **Mme. Chauchard**: The variations in salinity of estuaries easured *in situ* by the electrical conductivity.—**arcel Mascré**: The action of some fixing reagents the nucleus of the plant cell.—**A. Maige**: Observans on the phenomena of chloroplastogenesis and astidal regression in the cotyledons of various guminoseæ.—**A. Guilliermond**: The cytology of e Nematospora.—**A. de Puymaly**: A fixed Spirogyra, rennial and multiplying by layering.—**M. Bridel** and **lle. M. Desmarest**: A method permitting the exaction from the oil cake of bitter almonds of nygdaloside (amygdalin) and emulsin.—**E. Carrière** **d Brunet**: Contribution to the study of grape pip l.—**G. Guittonneau**: The influence of sulphur and e products of its solvation in the soil on nitrification. -**J. Legendre**: The battle between mosquitoes by e larval concurrence between zoophiles and andronilas.—**Maurice Azéma**: The excretion *in vitro* of ethylene blue by the renal vesicles of an ascidian.—**douard Fischer**: The relation between the reducing ower of sea water and the distribution of the ganisms of the coast line.—**Chevey**, **L. Roule**, and **lle. Verrier**: The interruption of the movement of lmon up rivers by the reduction of the amount of ssolved oxygen in the water course. If the dissolved ygen in a river falls below 6 c.c. per litre, salmon ill not ascend. Salmon appear to be more sensitive this respect than other fish.—**René Fabre** and **enri Simonnet**: Contribution to the physiological udy of glutathione by the method of perfusion. -**P. Delauney**: The biochemical synthesis of β-5, omosalicylglucoside. An attempt at the synesis of β-3-5-dichlorosalicylglucoside.—**Marcel Labbé**, **oubeau**, and **F. Nepveux**: The influence of nickel nd cobalt on the hypoglycæmic action of insulin the rabbit.—**G. Lavier**: The structure of the arabasal body in trypanosomes.—**Mme. Phisalix**: roperties of the serum of snakes belonging to the enus Coluber.—**Daniel Florentin**: The composition the air of the streets of Paris. A series of deterinations of the proportions of carbon monoxide and ioxide. The amount of impurity diminishes rapidly s the height above the ground increases.—**P. Lassaière**: The biological and therapeutic effects of the rosity of blisters.—**Jules Amar**: Mass action and ital defence.

The New Propaganda in Industry: its Nature and Practice. By J. Bertram Ward and W K. Crampton Chalk. Pp. 28 (London: The Technical Advertising Service, Ltd.)

Diary of Societies.

SATURDAY, January 28.

North of England Institute of Mining and Mechanical Engineers (Associates and Students Section) (at Neville Hall, Newcastle-upon-Tyne), at 3.—D. W Baron: Machine Mining at Ashington Colliery.

Royal Institution of Great Britain, at 3.—Prof. R W. Chambers: Some Tudor Biographers (2)

Institute of British Foundrymen (Newcastle and District Branch) (at Neville Hall, Newcastle-upon-Tyne), at 6 15.—D. Sharpe: Ramming Moulds by Sand-slinger.

MONDAY, January 30.

Institute of Actuaries, at 5.—J. M. Laing: New National Life Tables (1921 Census).

Royal College of Surgeons of England, at 5.—Prof W. E M Wardill: Certain Aspects of Cleft Palate, with Observations on the Causes of Defective Speech and the Remedies proposed for their Treatment.

Society of Chemical Industry (Yorkshire Section) (at Great Northern Hotel, Leeds), at 7.15.—Dr. F L. Usher and others: Discussion on The Phenomenon of Wetting and its Industrial Significance.

Royal Society of Arts, at 8.—Dr A. E. Dunstan: The Scientific Foundation of the Refining of Petroleum (Cantor Lectures) (III.).

TUESDAY, January 31.

Royal Society of Arts (Dominions and Colonies Meeting), at 4 30.—Lord Lovat: Migration in the Empire.

Royal Institution of Great Britain, at 5.15.—Prof. A. P. Newton: The Mercantile Empire, 1606–1783 (I.)

Royal Photographic Society of Great Britain (Colour Group), at 7.—L J. Hibbert: Light, Colour, and Colour Filters.

Institute of Chemical Engineers.

WEDNESDAY, February 1.

Royal Institute of Public Health, at 4.30.—Dr. N. Raw: Medico Legal Problems of Lunacy.

Royal Society of Medicine (History of Medicine Section), at 5.—Dr. G. A. Auden: (*a*) The Gild of the Barber Surgeons of the City of York; (*b*) Note on an Ancient Medical Manuscript in the Library of York Minster.

Royal College of Surgeons of England, at 5.—Prof. H. S Souttar: New Methods of Surgical Access to the Brain

Institution of Electrical Engineers (Wireless Section), at 6.—Capt P. P. Eckersley: The Design and Distribution of Wireless Broadcasting Stations for a National Service.

Institution of Electrical Engineers (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.—G. S. Evans: The Decorative Value of Electric Light.

Institution of Electrical Engineers (North-Eastern Centre) (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 7.—Dr. S. Z. de Ferranti: Electricity in the Service of Man (Faraday Lecture)

Royal Institute of British Architects, at 7.30.—C. H. B Quennell: House Building through the Centuries

Society of Public Analysts and other Analytical Chemists, at 8.—L. V. Cocks and E. Nightingale: The Determination of Butter in Margarine.—The Deposition of Metals on Copper from Cyanide Solution:—Dr. B S. Evans: I. A New Method for the Separation and Determination of Small Amounts of Lead.—Investigations into the Analytical Chemistry of Tantalum, Niobium, and their Mineral Associates:—Dr W. R. Schoeller and A. R. Powell: X. The Separation of Silica from the Earth Acids. XI. The Precipitation of Titanium by Tannin.—Prof. J. Reilly: The Determination of Carvone in Dill Oil.

Royal Society of Arts, at 8.—C. H. Wright: Modern Aspects of Rubber Cultivation.

Entomological Society of London, at 8.

Royal Society of Medicine (Surgery Section), at 8.30.—Pathological Evening.

Oil and Colour Chemists' Association.

Royal Microscopical Society (Biological Section).

THURSDAY, February 2.

Royal Society, at 4.30.—Prof. A. V. Hill: The Air Resistance to a Runner.—S. M. Manton: On the Embryology of a Mysid Crustacean *Hemimysis lamornae*.—Dr. R. J Ludford (*a*) Studies in the Mi chemistry of the Cell (I.); (*b*) Cytological Studies on the Viruses Fowl-pox and Vaccinia.—G. M Findlay Immunological and S logical Studies on the Viruses of Fowl-pox and Vaccinia.—G. Briggs: A Consideration of some Attempts to Analyse Gro Curves.—Dr. H. M Leake: Agricultural Value of Rainfall in Tropics.—C. Forster Cooper: On the Ear Region of Certain of Chrysochloridae.—Marion Hines: The Brain of Ornithorhynchus F. H. Edgeworth The Development of some of the Cranial Mus of Ganoid Fishes.—Dr F. W. R Brambell, Una Fielding, and A. S Parkes: Changes in the Ovary of the Mouse following Expo to X-Rays Part IV.

Linnean Society of London, at 5.—Major R W. G Hingston: Ani Life on Mount Everest.—W. T. Saxton: The Life-History Lunularia, with special reference to the Archegoniophore and Sporophyte.—R S. Adamson: Notes on the Vegetation of South Rhodesia.

Royal Institution of Great Britain, at 5.15.—Sir William Bra From Faraday's Note Books (I.): Ice and Regelation.

Institution of Electrical Engineers, at 6.—H. B. Poynder: So Practical Considerations in the Design of the Automatic Equipme for Heavy Traction Substations.

Royal Aeronautical Society (at Royal Society of Arts), at 6 30 Major H. N Wylie: The Design and Production of Steel Aircraft.

Chemical Society, at 8.—J W. Jenkin and Prof. C. H Desch So Experiments on Diffusion in Solid Metals.

Institution of Mechanical Engineers (Manchester Branch).—Fi Report of the Steam Nozzles Research Committee.

Institution of Mechanical Engineers (Glasgow Branch).—Prof. C. Hawkes: The Marine Oil-Engine (Thomas Lowe Gray Lecture)

FRIDAY, February 3.

Royal Astronomical Society (Geophysical Discussion), at 4 30 Longitude Observations and 'Shortt' Free Pendulum Clocks. Cha man: Sir Henry Lyons. Speakers: Dr. Jackson, Mr. Shortt, A. Hinks, and others.

Royal College of Surgeons of England, at 5.—Prof. E M Atkinson: The Pathology, Diagnosis, and Treatment of Abscess the Brain.

Geologists' Association (at University College) (Annual General Me ing), at 7.—Presidential Address: Further Aspects of the Mount Building Problem.

Royal Photographic Society of Great Britain (Pictorial Grou at 7.—Informal Meeting

Junior Institution of Engineers (Informal Meeting), at 7 30. D Kingsbury: Automatic Substations.

Philological Society (at University College), at 8.—Prof. E. Weekle Philological Notes.

Royal Society of Medicine (Anæsthetics Section), at 8.30.—A. Cowburn Death Occurring under Operation or Before Recove from Anæsthesia.

Royal Institution of Great Britain, at 9.—Prof E. C. C. Bal Photosynthesis.

Society of Chemical Industry (Manchester Section) (jointly wi Institution of the Rubber Industry) (at Engineers' Club, Mancheste —S. A. Brazier and Dr. L. R. Ridgway: The Influence of Zinc Ox on the Coefficient of Vulcanisation

SATURDAY, February 4.

Royal Institution of Great Britain, at 3.—H. C Colles: Music London from the Restoration to Handel (1660–1759) (I.)

Association of Women Science Teachers (Annual General Meetin (at St. Paul's Girls' School), at 4 30.—Sir John Russell The Grow of Crops: Applications of Botany and Chemistry to Country Li (Lecture)

PUBLIC LECTURES.

SATURDAY, January 28.

Horniman Museum (Forest Hill), at 3 30.—H. N. Milligan: Proofs Evolution in Animals and Man.

MONDAY, January 30.

University College, at 5.—Dr A. S. Parkes: The Internal Secretio of the Gonads. (Succeeding Lectures on Feb. 6, 13, 20, 27, an Mar. 5.)

University of Leeds, at 5.15.—Prof. E. V. Appleton: Wirele Methods of Investigating the Upper Atmosphere.

Gresham College, at 6.—G. P. Bailey: Modern Science and Dai Life: Mineral Oils.

East Anglian Institute of Agriculture (Chelmsford), at 7.—I Francis: The Poultry Industry: Developments and Prospects.

TUESDAY, January 31.

Bedford College for Women, at 5.15.—Prof. E B. Poulton: Rece Discoveries throwing New Light on some of the Commonest Insects.

WEDNESDAY, February 1.

University College, at 5.30.—C. Nowell: The Provision of Commerci and Technical Literature in the Smaller Public Libraries.—At 6.—Prof. A. L. Bowley: Measurement by Index Numbers—Theory an Application to Recent Economic History (Newmarch Lecture (Succeeding Lectures on Feb. 8, 15, 22, 29, and Mar. 7.)

SATURDAY, February 4.

Horniman Museum (Forest Hill), at 3.30.—Mrs. R. Aitken: Villag Life in High Castile.

SATURDAY, FEBRUARY 4, 1928.

Culture and Chemistry.

CRITICISM is an art to which Prof. H. E. Armstrong, as is well known, has given some attention. The opportunity occurring on the occasion of his lecture before the Royal Society of Arts on "Marcelin Berthelot and Synthetic Chemistry"—a full report appears in the *Journal* of the Society of Dec. 30—for the exercise of that faculty, was employed, in the main, in a manner such as cannot fail to arouse appreciation. As Sir William Pope, who opened the subsequent discussion, remarked, it would have been an easy enough task merely to give an account of Berthelot's life and of his manifold scientific activities, but to present a picture which should indicate how that work fitted in with the great scheme of progress and led to the present situation was an entirely different matter. That such a picture should be presented by one who has lived through that great epoch and has himself taken part in many of the big movements to which he necessarily referred, invested the discourse with a special degree of importance.

So much has been said and written in recent months in praise of the undoubtedly tremendous influence of that master-mind on the progress of scientific thought and achievement, that one may be forgiven for welcoming the condiment of informed, if sometimes mordant, criticism and analysis. It is evident that Prof. Armstrong still has no use for our modern system of chemical education—a system which we all freely admit to be far from perfect, but scarcely to be jettisoned on that account. We do not read original literature. We do not strive to shape our style on that of our forefathers. Indeed, we are losing the conception of culture in that domain, he says. There is, we submit, no lack to-day of either genius or philosophy. True, there may be more 'pottering' than yesterday, but may not that be ascribed to a greater abundance of potential potterers, perhaps even more than to the "present low level of academic impotence"?

We should do well, moreover, not to ignore the fact that the outward and visible signs of scientific culture, no less than of social culture, change with the times; they cannot be unaffected by the evolution of socialism (with a small 's') from individualism. More and more, too, such is the luxuriant growth in the garden of knowledge, one is consciously or unconsciously influenced by a mass-effect rather than by an individual plant, however venerable. In assessing the real importance of Prof. Armstrong's justifiable complaint, one may perhaps be permitted to take passing note of the other extreme of the matter, and to be reminded that there must be a modicum of truth in Mr. Stephen Leacock's amusing confession: "I'd like to take a large stone and write on it in very plain writing—'The classics are only primitive literature. They belong to the same class as primitive machinery and primitive music and primitive medicine,' and then throw it through the windows of a University and hide behind a fence to see the professors buzz!"

However, to return to the main theme of Prof. Armstrong's discourse, namely, Berthelot's pioneering labours at the foundations of our amazing modern edifice of synthetic chemistry. His multitude of thermochemical investigations was considered less worthy: "... he ceased to be a constructive artist; grasping the thermometer, he became a thermalist ... the slave of physical measurement." His work on biological problems and on chemical changes of importance to agriculture received less praise, although not quite so little as agricultural research of to-day. Berthelot's work in this subject "... shows him once more, in the main, as a chemist with undeveloped biological feeling." But in another field "it is clear that he set out upon his upward journey advisedly, bearing a banner inscribed with the device then entirely strange—'Organic Synthesis'"; alcohol, mustard oil, methane, acetylene, benzene, naphthalene, and anthracene were among the numerous compounds which were synthesised for the first time, and the idea of 'vital force' behind organic chemistry was disposed of for ever.

The very success of Berthelot's syntheses, suggesting that man may make all things, has done much, we are told, to hasten a debacle. To-day there is an "insensate desire" abroad to synthesise and manufacture everything. Prof. Armstrong becomes quite indignant at the idea of eating "margarine ... 'improved' with the aid of advitants from the livers of animals all and sundry." Berthelot, he declares, has given manufacturing chemists enough to do for some time to come without interfering with our food. In the discussion at the close of the lecture, however, Mr. Robert Mond put forward a point of view which might well be emphasised from the educational side: that in chemistry one can check one's own errors, and that chemistry *qua* chemistry may therefore be made the best tool for moral training that we possess.

EVERY physicist must at some time or other have felt some sympathy with the suggestion, coming in the first place from an ecclesiastical source, that research laboratories should take a compulsory vacation of some ten years or so, in order that a breathing space might be given in which it would be possible to assimilate the vast accumulation of knowledge of the past few years, and to consider its bearings and implications not only in science but also in philosophy. In fact, with the slight and obvious reservation that nothing in the bill should be regarded as applying to one's own laboratory, a measure on such lines would undoubtedly meet with considerable support. It is pretty certain that no one in the future will be able to know the whole of physics, as it was possible to know it twenty or thirty years ago, or to keep in touch with all its developments even to the extent of reading, at first hand, the original memoirs in which the new work is described. At the same time, the actions and reactions of different branches of the subject upon each other are as close as, or closer than ever.

The problem is a serious one for the university teacher. It is absurd that a student of physics should go out from the university without some knowledge of the developments of his subject during the last ten or twenty years, and yet one searches in vain through the standard curriculum for something which can safely be scrapped. The problem for the research worker, who has less time for reading than the student, is equally vital. He knows that some new discovery in some widely different branch of the subject may illuminate his own problems, and yet if he attempts to read all the journals which pour out from the press, he will certainly have little time for experimental work. Some large commercial laboratories, we believe, maintain a member whose sole duty is to digest this mass of material and to distribute the nutriment to the particular parts of the body politic where it is most appropriate. Most of us, however, belong to less highly developed organisms, where functional differentiation has not been carried so far. We must buy our food predigested if possible, and we are very grateful if some specialist, with a reasonable gift for clear exposition, will spare sufficient of his time to tell us what is going on in the particular part of the subject which he has made his own. Text-books and monographs must play an ever-increasing part in the dissemination of knowledge in physics, and the author of a really good book of this kind has earned the gratitude of his fellow-workers.

(1) Meyer and Schweidler's "Radioaktivität," which was first published in 1916, established itself as the standard book on this subject from the moment when it became generally available. After a lapse of rather more than ten years we welcome it again in its second edition. The very large amount of new material which it contains makes it practically a new work. The authors record that the number of entries in the author index has increased from 749 to 1561, and the number of papers cited from 2460 to 4380. It is clear from these figures that a prodigious amount of new work has had to be incorporated in the volume in order to bring it once more up-to-date, and no worker in the subject can afford to remain ignorant of this accumulation of new facts and data.

It may be said at once that the authors have done their work well. They have a talent for selecting the vital part of the work which they describe, and for giving the essence of it in a form which is concise without being obscure. The numerical data are unusually full, and above all, the book is excellently documented, so that the worker has no difficulty in tracing any piece of information to its source, and so obtaining further details if he requires them. The publishers, too, have played their part well. The printing is excellent, and the paper so good that although many of the diagrams are very small, they are quite clear. The book is one which all workers in the subject will need to consult and most of them will wish to possess.

(2) Eugène Bloch's "Thermionic Phenomena" is already well known in its French dress. Many of us have been grateful, in the past few years, for the very valuable series of "Conférences-Rapports," of which the book in its original form was one, and M. Bloch's account of this rapidly growing and important subject is quite up to the high standard of the series. Messrs. Methuen and Co. now provide us with an English translation, which students who are unable to read the original will be very glad to possess. The account of thermionic phenomena in this volume is neither so complete nor so detailed as Meyer and Schweidler's treatise on radioactivity, but it is an excellent introduction (probably the best we have) to the subject. There are fairly numerous references to the original documents, and Mr. J. R. Clarke, who has translated the work into very readable English, has thoughtfully provided two indexes, which were wanting in the original.

(3) "Dielectric Phenomena" is a book of quite a new kind, though we may see more of its type in the future. It might almost be described as a phenomenon in itself. Published on behalf of the British Electrical and Allied Industries Research Association, its object is not only to give but also to seek information. The problem of insulation and insulators is becoming very critical nowadays. Plans for distributing electrical energy throughout the length and breadth of the land by a network of high-tension wires are now reaching maturity, and both for its safety and its efficiency the scheme must look to its insulators. Again, both in pure research and in medical work, there is a demand for higher and still higher voltages. The 100,000 volt apparatus which was practically standard in radiological departments a few years ago, is being replaced by sets capable of producing 200,000 volts, and there is no suggestion that the demand for 'volts' has reached its limits. Here, again, insulation is the vital problem.

The British Electrical and Allied Industries Research Association is clearly very much alive to the situation, and to the very unsatisfactory nature of our present knowledge of the subject. Mr. Whitehead, on behalf of the Association, has made, in this volume, a critical résumé of what is already known, or surmised on the subject, and one can only agree with his conclusion that there is scope for much more work, both experimental and theoretical.

Although our knowledge is admittedly very imperfect, Mr. Whitehead has succeeded in bringing together quite an important mass of data, much of it from periodicals which are not usually consulted by the physicist, and anyone interested either in insulation or in high tension discharge (for the book is mainly concerned with what happens when an insulator, and in particular a gaseous insulator, breaks down) will find here most of what there is to be known on the subject. This is, we believe, the first occasion on which a research association has published one of its précis for the benefit of scientific workers generally. Let us hope that they will reap a harvest of new discoveries.

(4) It is no disparagement to the authors of the volumes just reviewed to say that the most interesting has been reserved until last. Text-books and monographs are our necessary 'bread and butter' in these days; the reports of the triennial Solvay Conferences are real 'jam.' It is not so much the possession as the pursuit of knowledge which fascinates us; and the best written histories cannot rouse in us the same lively interest as a daily paper at a time when great events are afoot. In these Solvay reports we have, as it were, knowledge in the making; we can watch the interplay of experiment and hypothesis; and can even, as uninvited guests, enjoy the fun of speculating as to which, if any, of the numerous suggestions put forward by the eminent physicists present will prove to be nearest to the mark. The subject of the present report, "The Electrical Conductivity of Metals," lends itself particularly to this game, for there is scarcely any part of theoretical physics in which there is more uncertainty. Prof. Lorentz invites us to consider the electrons in the metal as constituting a perfect gas. Prof. Lindemann prefers to regard them as a perfect solid, and puts up a vigorous defence for his hypothesis. Prof. Bridgman, in a very excellent résumé of the subject, invites us to consider some dozen other theories, which have been mooted from time to time, besides suggesting a new one of his own. It is all very exciting, and excellent reading.

We should be wrong, however, if we left the impression that the volume was all 'jam.' Like its predecessors, this Solvay report contains some of the best summaries which we have of the present state of knowledge in the subjects with which it deals. In addition to Prof. Bridgman's report, which has already been mentioned, we have a very illuminating account by Prof. Lorentz of the application of the electron theory to metals, a paper by Dr. Rosenhain on the internal structure of alloys, and an account written by the late Prof. Kamerlingh Onnes of his work on supra-conductors.

The mention of the name of this great pioneer, whose death we had to deplore some time ago, brings me to the one complaint which I have to urge. The present volume does not record the proceedings of the conference held last year, but of its predecessor of 1924. Even admitting that the work of editing a volume of this kind is not light, and that it is not the easiest of tasks to extract corrected proofs from distinguished men, the interval of three years between the meeting of a conference and the publication of its report seems unnecessarily long. It would be a real benefit to science if these reports, which are always looked forward to eagerly, could be published at any rate within twelve months of the date of the conference. It says much for the quality of the work contained in the present volume that it has lost so little interest by the unfortunate delay.

J. A. CROWTHER.

Nature of Cytoplasmic Inclusions.

Symbionticism and the Origin of Species. By Prof. Ivan E. Wallin. Pp. xi + 171 + 4 plates. (London: Baillière, Tindall and Cox, 1927.) 13*s.* 6*d.* net.

IT is now at least eight years since there have been any flutterings in the cytological dovecot. Everyone had settled down to a cell containing a nucleus with chromosomes, karyoplasm, karyosome, and plasmosome, and a cytoplasm with centrosome, Golgi bodies, and mitochondria. If there were malcontents, they had been silenced by the shock effect of the vast and ever-increasing international literature on the cytoplasmic inclusions. In the field concerned with the intra-nuclear bodies, the chromosomes have attained respectability even in the views of those physiologists who cannot understand such a simple thing as the chromosome theory.

Now in this last year there have been ripples in the hitherto calm waters. First, there has been the re-blooming of the Merseyside cytological plant, under the care of Prof. Charles Walker, who, to the admiration of several chemists and at least one palæontologist, has, so to speak, demonstrated, with the aid of a tin of condensed milk and some water, that there is no such thing as a cow (*Proc. Roy. Soc.*, vol. 101, B, 712). Secondly, Dr. Parat has discovered that Golgi, Cajal, Rio Hortega, E. B. Wilson, Da Fano, Ludford, Bowen, Hirschler, Hyman, Doncaster, Voinov, Nassonow, and many other cytologists and histologists, have mistaken mitochondrial bodies ('lepidosomes') for the true Golgi bodies, and that Dr. Parat's veritable cell vacuole is the true Golgi apparatus; and we have the word of the distinguished human anatomist, Dr. Woollard ("Recent Advances in Anatomy"), that Dr. Parat is correct!

Lastly, we note the issue of the book under review. Dr. Wallin, professor of anatomy in the University of Colorado School of Medicine, does not cry 'artefact' at us, as does Prof. C. Walker, nor does he mention the 'vacuome' of Parat especially —he merely asks us to believe that the mitochondria (and the Golgi bodies possibly also, being modified mitochondria) are bacteria ('symbiotes'). The origin of species has taken place largely owing to the activity of these bacterial symbiotes, and the process is called 'symbionticism,' a new and horrid word. Dr. Wallin, unlike Dr. Walker, is prepared and ready to allow us any cytoplasmic inclusions we like, just so long as we do not forget that they are bacteria. He does not mind whether Golgi's Golgi apparatus is the real Golgi apparatus, or whether Dr. Parat's rival Golgi apparatus is the real Golgi apparatus.

Seriously, however, Dr. Wallin finds that mitochondria may be minute spheres or rods (like bacteria), may stain in fuchsin and such dyes (like bacteria), may divide by binary fission (like bacteria), may grow on media (like bacteria), and, finally, that all stages in the establishment of 'symbionticism' may be found in such organs as cockroach eggs, plant roots, and cephalopod light organs, to mention but a few. 'Symbionticism' is the key, according to Dr. Wallin, to the diversity of animal life.

Now it may be said at once that it is not easy to get a definition of a bacterium which would not equally well apply to a mitochondrion—at least the reviewer has not met the bacteriologist who could give a satisfactory and discriminating definition. This is the strength of Dr. Wallin's position. On the other hand, it is possible for the cytologist to give a definition of a mitochondrion which may exclude all bacteria. For example—a mitochondrion is a minute sheathless intra-cellular body never containing chromatinic particles, and capable of fusing with other mitochondria to form structures such as the uninterrupted tail of a spermatozoon.

Now, Dobell showed years ago that in large bacteria chromatic particles exist. No mitochondria large or small ever contain such particles. Then, too, no bacteria are known to fuse into a mass to form one long structure, like a sperm tail sheath. Dr. Wallin will find that the field of spermatogenesis alone will provide facts which make his position untenable. We believe that the case he makes for the growth of mitochondria on nutrient media is unsatisfactory, though even if the evidence had been complete, this would not convince the reviewer that mitochondria are necessarily bacteria.

The similarity between the techniques for staining bacteria and Golgi bodies and mitochondria can be admitted if at the same time it be pointed out to Dr. Wallin that there never was a case where the two types of structures (symbiotic or parasitic bacteria and mitochondria) could not be differentiated easily by current techniques. No one has ever described any sort of sheath on mitochondria, and the latter are more fragile than the general run of bacteria. The similarity in size and shape between bacteria and mitochondria means little. The case Dr. Wallin tries to make for a similarity of chemical constitution between bacteria and mitochondria is completely unconvincing.

J. Brontë Gatenby.

The Activated Sludge Process of Sewage Treatment.

The Activated Sludge Process. By Arthur J. Martin. (Reconstructive Technical Series.) Pp. xiv + 415 + 37 plates. (London: Macdonald and Evans, 1927.) 30*s*. net.

THIS book may be described as an amplification and bringing up-to-date of the paper read by Mr. Martin before the Institution of Civil Engineers a few years ago, in which he brought together established facts and results contained in a great number of scattered papers dealing with the subject of the activated sludge process.

Chap. i. details the early work on the forced aeration of filters and various methods of aeration of sewage in tanks, including the Lawrence and Fowler experiments. Chap. ii. is concerned with the experiments of Arden and Lockett, many extensive extracts being given from the papers by these workers. Full-sized working units at Withington and Davyhulme are described in Chap. iii, with drawings and photographs, analyses, and useful data respecting air consumption and volume of sewage treated.

The diffused air system is fully dealt with in Chap. iv., a number of British works being fully described, with plans and sections: a good photograph is given in this chapter, showing an aerial view of the Coventry works. The next three chapters are devoted to the subject of mechanical agitation , the Sheffield, simplex, spiral flow, and others being described at some length.

A short chapter—Chap. viii —records the progress the process has made in England, as shown in the annual reports of the Ministry of Health, whilst the next chapter deals with the process in America and Canada, the Milwaukee, Chicago, Houston, Indianapolis, and other plants being fully described and illustrated with plans and photographs.

Chaps. x. and xi. deal respectively with the theory and the requirements of the process, and it may be questioned whether, all things considered, these two chapters would not come in more suitably at an earlier stage. In Chap. x. the sensitiveness of the process to changes in the character of the sewage, as, for example, those brought about by influxes of certain trade wastes, is emphasised. In the latter chapter, the essential requirements of the process, namely, oxygen, suitably conditioned sludge, and effective circulation of the sludge and liquid, are carefully described, frequent quotations from various well-known authorities being made.

Chaps. xii. to xiv are concerned with need for preliminary treatment, alternative modes of working, and diffusers ; whilst Chap. xv. deals with the important question of design of tanks, the Clifford inlet being described and illustrated The next three chapters treat of air compression, loss of pressure in air mains, and appliances for mechanical agitation. Power required for agitation receives notice in a short chapter (xix.) of three pages.

The rather controversial question of comparison of methods of agitation has eleven pages devoted to it in Chap. x., the advantages and drawbacks of various methods being carefully discussed. The author states that the air-blowing method, being first in the field, has naturally received more attention than mechanical agitation.

Chap. xx. contains eleven pages descriptive of a combination of methods, Imhoff's Essen-Rellinghausen experiments on the use of diffused air in conjunction with mechanical agitation being described and illustrated, together with the Kettwig submerged contact aerator, in which the aerator consists of brushwood, air being supplied by a moving pipe.

Chaps xxii. and xxvi. deal with position and outlook, cost of process, reduction of cost of process, factors affecting cost of power, and possible lines of advance.

The bugbear of sludge disposal is very fully and usefully discussed in Chap. xxvii., 34 pages being given to this most important question. The author points out that the bulk of activated sludge—owing to its high water-content—is frequently more than 1 per cent., and sometimes as great as 6 per cent. of that of the sewage from which it originates. He considers that if it is found practicable to apply activated sludge direct to land in its wet state, one of the chief obstacles to the adoption of this process of sewage treatment will have been removed.

The final short chapter of six pages deals with latest developments in the process. Six appendices follow, and an exceptionally complete, useful, and well-arranged bibliography relating to the literature of the activated sludge process.

A list of authors cited and a comprehensive index complete the book.

The book is well written and illustrated, and the printing is good. The author may fairly claim to have accomplished what he set out to achieve, namely, " to present the leading opinions on both sides, and so far as possible, in the words of those responsible for them." The labour involved in bringing together in readable form the salient facts and features of the activated sludge process from the voluminous literature relating thereto must have been considerable, and Mr. Martin's book should prove most useful to engineers and others interested in sewage treatment.

G. BERTRAM KERSHAW.

A Ruthless Republic.

The Life of the White Ant. By Maurice Maeterlinck. Translated by Alfred Sutro Pp. 213. (London . George Allen and Unwin, Ltd., 1927.) 6*s*. net.

IN taking up any work on natural history by Maurice Maeterlinck, we know that we may expect to find a picturesque compilation of facts for the most part well authenticated, recounted in an agreeable style, and diversified by comments of a moralising character which, though not always convincing, are generally not without interest. The present book is in these respects true to type. The author has been to the best sources for his facts ; his philosophical deductions bear the impress of a mind which, if somewhat uncritical in method, is yet sound in its estimate of the importance of human life and destiny.

The systematics of the remarkable group of insects here dealt with are but lightly touched upon. The reader will find nothing to replace the treatment of morphological detail which is the concern of ordinary text-books. It is the constitution, economy, and polity of the termitarium, the extraordinary differentiation of the various descendants of a single pair, the pitiless subordination of the apparent well-being of the individual to that of the community, that principally engage the author's attention. A matter of which he treats at considerable length is the symbiotic relation between termites and their intestinal protozoa, the recognition of which we owe to the recent investigations of L. R. Cleveland.

The architecture of the common habitation is briefly described, and sketches are given of the distinctive characters and behaviour of the workers, soldiers, and royal couple. But the author's speculations on the origin and development of the various instincts that combine to make up the life of the termite society are vitiated by his persistent attempts to attribute foresight and intelligence to its constituent members. The key to the problem is to be found, no doubt, in the comparison of the more or less advanced stages of elaboration reached by the development of different species, under the influence of natural selection. Considerations of this sort, however, do not appeal to M. Maeterlinck, who appears to prefer to have recourse to the supposed "intelligence and will" of the termites. Thus, on the subject of their nutrition he asks, "Why not recognise that they may themselves have found it more convenient, preferable, to install digestive protozoa in their own bodies, so as to be able to give up vegetable mould and eat whatever they choose?" Then again, in reference to the mushroom-cultivating species, he says:

> "The termites must have noticed that such mushrooms provided a far richer, more certain and more directly assimilable food than vegetable mould or waste wood, and possessed the additional advantage of helping them to get rid of the embarrassing protozoa whose weight was becoming so oppressive. Thenceforward they proceeded systematically to cultivate these cryptogams."

It is true that M. Maeterlinck adds, "Evidently, or at least probably, all this is due merely to chance"; but his reference in the same passage to the method of cultivation in the neighbourhood of Paris shows that his attribution of conscious ingenuity and method to the termite is deliberate and intentional. It seems, in fact, from this place and from many allusions to the *anima mundi*, that he would not be disinclined to apply to the 'white ants' what Vergil says about the bees:

> "his quidam signis atque haec exempla secuti
> esse apibus partem divinae mentis et haustus
> aetherios dixere."

F. A. D.

Our Bookshelf.

An Introduction to the Scientific Study of the Soil. By Prof. Norman M. Comber. Pp. 192. (London: Edward Arnold and Co., 1927.) 7*s.* 6*d.* net.

THE great advance in our knowledge of soil physics and chemistry during recent years has been accompanied by a flood of literature which renders it increasingly difficult for any worker to obtain a comprehensive view of the subject without the expenditure of undue time and labour. Prof. Comber is therefore the more to be congratulated, in that he has succeeded in presenting the salient features of the subject in such a way that not only students (for whom the book is primarily intended) but also advanced research workers will find much illumination and assistance therefrom. His exposition is masterly, a few words conveying the essentials of each point without burdening the reader with details, which can be found when necessary in the original papers, to which an adequate bibliography is provided. One striking feature is the simple explanation of common phenomena which are not often thought about, as, for example, why seeds fail to grow if planted too deeply.

After dealing briefly with the relations between the soil and the plant, the origin and development of different soils are described under the heading "soil genetics," and then the components and attributes of soils are treated individually in more detail. This leads up to an account of various bases of soil classification, from the agricultural and the scientific viewpoints, special attention being given to the work of the Russian school of investigators and to the United States work on soil profiles. Various experimental methods for comparison of the effect of different types of soil treatment in the laboratory and the field are outlined, with indications of their relative value. An unusual feature is introduced in the form of practical suggestions to the student as to the best methods of utilising the literature of the subject, a matter which seems simple at first sight but is apt to involve the inexperienced in a welter of information which obscures the end sought. This book, with its clarity of concentration of a complicated subject, should prove of the utmost value to all who are working on the soil, whether from the biological, chemical, or physical point of view.

The Propagation of Electric Currents in Telephone and Telegraph Conductors. By Prof. J. A. Fleming. Fourth edition, revised and extended. Pp. xv+422. (London: Constable and Co., Ltd., 1927.) 21*s.* net.

THE addition of a new chapter to this book has greatly increased its usefulness. The enormous improvements in the design and manufacture of submarine cables, and the advances made in the construction of telephone and telegraph cables, make some account of them essential to the student. The use of powdered iron instead of iron wire in the cores of 'loading' coils has practically eliminated eddy current loss without lowering appreciably the permeability of the core. The extension of the usefulness of the cable by means of 'phantom' circuits can only be obtained by almost perfect balancing of the various circuits. It was discovered in American research laboratories that an alloy of nickel and iron containing more than 30 per cent. of nickel has remarkable magnetic properties. Permalloy has a composition of nearly 80 per cent. of nickel and 20 per cent. of iron. At vanishingly small magnetising forces permalloy may have a permeability of 13,000, which is more than thirty times as large as that of the best soft iron. Permalloy may even be saturated when subjected to the earth's magnetic field.

It is found that when a submarine cable is suitably covered with permalloy tape, the speed of transmission of the messages can be increased ten times. A brief mention is made of the structure and mode of using thermionic repeaters, the use of which has greatly increased the range of telephony and greatly reduced the cost of the conductors. The development of carrier wave multiple telephony is also described. By its means several independent conversations can be conducted simultaneously on one line. It is satisfactory to note that practically all these inventions are the immediate outcome of the application of theory To the student especially this book will be of great value.

Die seltenen Erden vom Standpunkte des Atombaues. Von Prof. Dr Georg v. Hevesy. (Struktur der Materie in Einzeldarstellungen, herausgegeben von M. Born und J. Franck, Heft 5.) Pp. viii + 140 (Berlin: Julius Springer, 1927.) 9 gold marks.

The discovery by Johann Gadolin in 1794 of the mineral gadolinite opened up a new and difficult field of investigation, which has had an important bearing on the theory of atomic structure. The problem of fitting the rare-earth elements into the periodic system was only partly solved when Moseley's work revealed the total number as well as the positions of members of the cluster. Hevesy shows how Bohr's theory of atomic structure provides a key to their mysterious behaviour, and the well-known fact that, chemically, yttrium lies in the midst of its higher homologues becomes intelligible; for whilst the valency-electrons of tervalent lanthanum are more remote from the nucleus than those of yttrium, and are therefore less firmly bound, other conditions prevail in higher members, where valency-electrons lie at a deeper quantum level.

Amongst other physical properties the paramagnetism of ions is discussed at length, and is shown to exist only where the distribution of valency-electrons is anomalous, but the latter are unusually deep-seated between cerium and lutecium. This is held to account both for chemical similarities and chemical irregularities in the cluster. Now since no satisfactory data are as yet available of ionisation potentials with which to judge the firmness with which these electrons are held, one has to draw conclusions from the molecular volumes of analogous compounds. Though apparently irregular, the results are in agreement with the requirements of Bohr's distribution. Thus a steep rise in value in passing from scandium to lanthanum is followed by a gentle fall from lanthanum to lutecium.

The second part contains a useful account of the chemical properties of compounds and concludes with a historical survey of the subject.

Directing Mental Energy. By Dr. Francis Aveling. Pp. x + 276. (London: University of London Press, Ltd., 1927.) 8s. 6d. net.

This is a peculiarly constructed book. The author seeks to show how we may economise our expenditure of energy, of which we possess only a limited stock, as a partial solution of the problem 'How to make the most out of life'; as if a conscientious application of the proverbial injunction 'to take care of the pence' were an important secret of happiness. Yet, fundamentally, Dr. Aveling is more concerned with the problem of spending wisely than with the rather negative emphasis on economy and on the avoidance of waste from which he starts.

The title and the introduction suggest a much more profound and philosophical treatise than the author has given us. Consequently, in parts, the treatment seems somewhat inadequate; some of the topics, especially those on industrial and vocational psychology, are dealt with too broadly for a work of this kind. Dr. Aveling, however, sees unity in the diversity of our daily life and invokes the laws of energy to explain it. Even such a spontaneous expression of human impulses as is found in play is regarded as having its 'why and wherefore' in the constancy of human energy. The book is decidedly interesting, though the author's thesis will not be acceptable to all psychologists.

Mexican Architecture of the Vice-Regal Period. By Walter H. Kilham. Pp. 223 + 84 plates. (New York and London: Longmans, Green and Co., Ltd., 1927.) 21s. net.

Hispano-American architecture is not likely to be a subject with which very many European readers are familiar. It is, however, well worth study, on account of its innate beauty and form. Its period of development extends from the middle of the sixteenth century to the beginning of the nineteenth, when Spanish domination came to an end. Mexican architecture in its main lines followed that of Spain at a time when the Renaissance style was developing in the mother country. It presents, however, a course of independent development of its own, which comes out in many features, but especially in the use of coloured tiles. Of its peculiarities, many are due to the employment of native workmen, Indians, who themselves had an architectural tradition behind them, and considerable artistic taste of their own. It is this which gives Spanish-American architecture an individual interest as a subject of study. Mr. Kilham's informative sketch of its history is clear in its description and exceedingly well illustrated.

The Nature and Function of Golgi Bodies.

IN view of Prof. Charles Walker's letter in NATURE of Jan. 21 on the nature and function of Golgi bodies, perhaps I may be allowed to summarise, briefly, the reasons why most cytologists have come to regard the Golgi apparatus as a definite cytoplasmic structure:

(1) The Golgi apparatus can be seen in certain living cells, for example, spermatocytes of Helix (Platner, Murray).

(2) A positive picture of the apparatus can be obtained by the silver and osmic methods (Cajal and Kopsch, and their numerous modifications); also a negative picture results when good cytoplasmic fixatives are employed. Anyone can prove this by trying the osmic and silver methods with cells of the epididymis, or pancreas of the mouse, and comparing the results with material fixed in osmic acid, and counterstained with a plasma stain. In suitable osmic preparations the mitochondria can also be counterstained, and then appear the same as in the living cell, so the argument that cell structure has been distorted by the technique is untenable. It has been shown by Karpova that the Golgi bodies in the spermatocyte of Helix can be stained with Sudan III, after the bichromate treatment of Ciaccio, and Weiner has been able to demonstrate the apparatus by the same method in epithelial cells of the intestine.

(3) The Golgi apparatus has a characteristic form in different types of cells; for example, in most neurones it is a network, while in fibroblasts it forms a compact cluster around the sphere.

(4) It has been shown by a large number of workers (see the reviews of Bowen, *Anat. Rec.*, vol. 32, 1926, and Jacobs, *Ergeb. d. Biol.*, vol. 2, 1927) that there is a definite correlation between the form of the Golgi apparatus and the functional activity of the cell. Thus the form of the apparatus varies during secretory activity in gland cells. In neurones it is altered as the result of injury (Cajal, Penfield); while phosphorus poisoning induces well-marked changes in cells of the pancreas (Cowdry). During gametogenesis, also, it undergoes characteristic changes (Gatenby, Bowen, Brambell).

(5) The secretion granules of gland cells arise in relationship with the Golgi apparatus. Nassonov and Makarov have shown that acid dyes such as trypan blue when injected subcutaneously collect in liver and kidney cells in that part of the cytoplasm where the Golgi apparatus is situated. The droplets of dye accumulate, therefore, in the region of the Golgi apparatus, so the apparatus cannot be a mere condensation of lipoids around droplets as Walker has suggested.

Prof. Walker's argument is based upon a fallacy, that things which look alike are necessarily the same. Every elementary student of physiology knows that models can be set up to imitate amœboid movement, cell division, and growth (artificial osmotic membrane experiments), while cell-like structures with nuclei can be imitated with gelatine solutions. Does this disprove the reality of these vital phenomena? Since Prof. Walker has produced artificial structures, which he says look like Golgi bodies, this no more disproves the existence of the Golgi apparatus in living cells than the production of artificial cells with nuclei disproves the reality of cell structure. Prof. Walker's work seems rather to confirm the view held by most cytologists that the Golgi apparatus is of a lipoidal nature.

The Spectrum of the Corona.

A CORRESPONDENCE, which may be important, has been found between the 'unknown' spectral lines of the solar corona and the spectrum of argon. It has been found possible to connect about two-thirds of the coronal lines given by Campbell and Moore with the argon lines and terms in Meissner's recent investigation.

There are 18 lines directly identified. The lines in the argon spectrum immediately before and after the selected one are, in each case, well removed from the selected line, compared to the discrepancy between the coronal and the argon wave-numbers. In any case this latter discrepancy is within the accuracy to which the coronal lines are known.

Space does not permit of giving the complete tables, but a few typical examples will be quoted:

The average disagreement is 2 wave numbers; the maximum is 5 (allowed only in the cases where the determination of the wave-length is correspondingly uncertain) and there are half-a-dozen lines where the agreement is accurate within one wave-number. On the other hand, the average distance to the nearest line in the argon spectrum is 30 wave-numbers. For example, the coronal line of wave-number 27443 has, corresponding to it, an argon line, 27441. The argon lines closest by, and to either side, are 27391 and 27507. The selected argon line has the designation $1s_4 - 4p_8$. Consider the two coronal lines of wave-numbers 19533 and 17860. It was recognised that the difference in the wave-numbers was the same as the interval between the $2p_8$ and the $2p_3$ terms in argon, and the argon wave-numbers given by $2p_8 - 6s_1'''$, and by $2p_3 - 6s_1'''$ are these two coronal wave-numbers to within 1 wave-number.

The lines directly identified include most of the strong lines of the corona. Ten other coronal lines are found to be expressible as combinations of Meissner's term values. Thus a line of wave-number 24468 may be compared with the wave-number 24470 given by the combination $1S_3 - 4d'_4$. A coronal line at wave-number 18852 is given by $2p_4 - 9s_4 = 18852{\cdot}58$ and by $2p_5 - 7s_1'' = 18852{\cdot}17$. This line, λ5302·9, is the brightest line in the coronal spectrum; and the fact that its wave-number is given quite accurately by two different combinations of terms (that is, by two different possible changes in the state of the radiating centre), may be connected with this fact.

Because of the presence of Ca II in extremely high levels of the chromosphere, it was thought that the coronal lines might be attributed to this substance or to Ca III as suggested by Pannekoek. However, a comparison with J. A. Anderson's tables of the calcium spectra gave no very suggestive agreement.

The implication that argon exists in the sun is not borne out by other solar observations; but it is to be remembered that a given substance may be abundantly present in the sun, and yet because the external conditions do not bear a certain definite relation to its ionisation potential—as required by the Saha theory—the spectrum may not appear at all. It is not beyond possibility that conditions of temperature and pressure in certain regions of the corona are favourable not only for the production of the lines of a given element but also for the appearance of groups of lines which are not given by ordinary laboratory methods of excitation.

A more detailed presentation will appear soon in the *Astrophysical Journal*. IRA M. FREEMAN.

A Simple Rainfall Law.

I HAVE recently prepared statistics giving the maximum total rain falling on any *n* consecutive days, for selected stations in Ceylon, and over certain periods. These figures, with a discussion, are being published as a paper, "Heavy Rainfall in Ceylon," in the *Transactions of the Engineering Association of Ceylon* for 1927.

In the course of this investigation I discovered a very simple law, which Ceylon rainfall seems to follow very closely, but which, so far as I am aware, has not been pointed out elsewhere.

Consider the maximum value of the total rain falling in *n* consecutive days during any one year. Let R represent the mean of a number of such values for different years; then, if this mean is taken over a sufficient number of years, we have

$$R = Qn^K,$$

where Q and K are constants for any particular station and period of years, and n is small. This formula holds with remarkable accuracy, when the means are taken over, say, 40 years or more.

In the table below, figures are given for four stations. The first row for each station gives R, the actual mean yearly maximum rainfall, in inches, extracted from the daily records of that station.

STATION.	n =	1	2	3	4	5	6	7	8	9	10	Q	K
Avissawella (47 years)	Actual mean maxima	5 89	8 16	9 66	11 20	12 59	13 94	15 17	16 13	17 15	18 09	5 68	0 502
	Theoretical mean maxima, $=Qn^K$	5 68	8 05	9 87	11 40	12 75	13 97	15 10	16·15	17 12	18 06		
	Percentage excess of actual	+3 6	+1 4	−2·1	−1 8	−1 3	−0 2	+0 5	−0 1	+0 2	+0 2		
Haldummulla (40 years)	Actual mean maxima	4 64	6·46	7·97	9 26	10 46	11 46	12 42	13 10	14 08	14 84	4 58	0·510
	Theoretical mean maxima, $=Qn^K$	4 58	6 52	8 02	9·29	10 40	11·42	12 35	13 23	14 04	14·83		
	Percentage excess of actual	+1 3	−0 9	−0 6	−0 3	+0 6	+0 3	+0 6	−1 0	+0 3	+0 1		
St. Martin's (37 years)	Actual mean maxima	10 34	15 38	19 16	21 54	24 31	27 00	29 21	31 34	33 45	34 97	10 51	0 523
	Theoretical mean maxima, $=Qn^K$	10 54	15 15	18 74	21 78	24 47	26 92	29 17	31·30	33 27	35 16		
	Percentage excess of actual	−2 0	+1·5	+2 3	−1 1	−0 7	+0 3	+0 1	+0 1	+0 5	−0 5		
Jaffna (56 years)	Actual mean maxima	5 17	6 95	7 93	8 78	9 53	10 24	10 93	11 42	11 88	12 45	5 24	0 376
	Theoretical mean maxima, $=Qn^K$	5 24	6 79	7 91	8 81	9 58	10 26	10 87	11·42	11 94	12 42		
	Percentage excess of actual	−1·4	+2 3	+0 2	−0 3	−0 5	−0 2	+0 5	0 0	−0 5	+0 2		

The columns headed Q and K give the constants deduced from these straight lines, while the second row for each station gives values of Qn^K, computed from these constants. The third row gives the percentage excess of the first row over the second, and it will be seen that the agreement is remarkably close.

As the stations examined represent a considerable diversity of rainfall types, depressional, north-east monsoon, south-west monsoon, and diurnal local circulation, it seems probable that this is a general law, universally applicable, in which case it affords a means of classifying rainfall by two numbers only. Such a simple numerical classification may be of value in regional studies of precipitation.

I have submitted a paper on this subject to the *Ceylon Journal of Science*, and this will appear in the next issue of Section E, while further investigations on the variations of K and Q, over Ceylon, will be undertaken. H. JAMESON.

Dec. 27.

The Two Calories.

I HAVE read with appreciation Mr. Marks's letter in NATURE of Jan. 14. May I recall that fifty-seven years ago Thomas Muir, the mathematician (now Sir Thomas Muir), suggested the names therm and kilotherm for them (see NATURE, vol. 1, p. 606). Since then the Gas Companies have appropriated the name therm and defined it as 100,000 British Thermal Units. It seems to me that from the scientific, the engineering, and the practical points of view, the best units for heat are the kilowatt-hour, its multiples and submultiples.

ALEXANDER RUSSELL.

Faraday House,
Southampton Row, W.C 1.

THE confusion between the two calories referred to by Mr. Marks in NATURE of Jan. 14 would be made worse by his suggestion that the kilogram calorie should be written as Kalorie, since it could then be confused with the so-called Ostwald calorie—a unit which should never be used and is now obsolete, because the latter is denoted by *K*. The matter of differentiating between the gram and kilogram calories was considered by the Bureau of Chemical Abstracts some little time ago, and the chairman of the board, Prof. J. C. Philip, informs me that it was decided to use 'g. cal.' and 'k. cal.' for the two units. It is highly desirable that this method should be generally adopted, since much confusion and even error is undoubtedly caused by the use of 'cal.' and 'Cal.' The question of the unit calorie, whether 15° or 20°, etc., adds a further source of confusion to very accurate work, and when this is known it may be stated as a suffix, say g. cal $_{15^\circ}$, as is also done by the Bureau of Chemical Abstracts.

The whole matter of physico-chemical symbols was considered some time ago by a small committee of the Chemical Society, of which I was a member, and some trouble was taken with it. The results, however, which were handed over to some international body or other, have disappeared without trace.

A Proposed Biological Flora of Britain.

IN the preface to the first edition of the "Students' Flora," published in 1870, Sir Joseph Hooker expressed the hope of being able to undertake a companion volume in which "the physiological and morphological observations" on British species should be recorded. Ever since that time this idea has been in the minds of botanists, but so far no serious attempt has been made to bring the project to fruition.

Such aut-ecological data are of great value, not only for their own sake, but also for the progress of the study of plant communities, which is greatly hampered by the lack of information respecting the life-histories and biotic relations of their constituent species. Further, until such data are available, it is useless to attempt to unravel the complex tangle of factors involved in the phenomenon of competition.

Much relevant information is scattered through the literature but is comparatively inaccessible; much, too, is known to field naturalists, but perishes with them. The collection of the published data, and such original observations as are available, will not only be valuable in itself, but will also provide the surest means of bringing to the notice of students the many lacunæ that require to be filled.

The council of the British Ecological Society has had the matter under consideration, and at the annual meeting on Jan. 7, the Society decided to undertake the publication of a British biological flora which should embody the available data regarding the biology and ecology of the native and naturalised British species.

The writer, who has been making observations and collecting data of this character with reference to British woodland species for several years past, has undertaken the preparation and editing of the work, but it is manifestly a task that can only be successfully accomplished by the active co-operation of botanists, professional and amateur alike, throughout the country.

A schedule indicating the scope of the projected work has been prepared by the writer and will be sent to anyone willing to assist.

(President, British Ecological Society).
University College, London.

Polarisation of Radio Waves.

IN some recent work on this subject carried out for the Radio Research Board, the following interesting results have been obtained in connexion with the propagation of long waves (14,350 metres).

In the course of simultaneous observations over a period from one hour before until one hour after sunrise of the same transmission from St. Assise by two stations, Slough and Aberdeen, roughly 400 and 1000 km. from it and approximately on the same great circle, it has been found that in the period preceding sunrise the wave arriving at the nearer station is plane polarised, with its plane of polarisation rotated in a clockwise direction when looking in the direction of propagation, whereas at the more distant station the rotation is anti-clockwise. By the time of sunrise both these abnormal polarisations have gradually decreased and disappeared, and in some cases at the nearer station the space wave appears to have entirely vanished also. About half an hour later, however, the space wave reappears at the nearer station, but this time with left-handed polarisation.

This persists with varying intensity throughout the day, again disappearing about 15.00 G.M.T., when the right-handed polarisation returns for the night.

It has also been shown that the wave reaching the far station has started from the transmitter at practically the same angle of elevation as the wave to the near station, and that its downcoming angle at the far station is comparatively steep. Internal evidence is strongly against the idea of a twice-reflected wave, mainly because the variations of direction and intensity observed are too great to fit in with the roughly known values of the reflecting power of the layer for a single reflection; and there seems a strong probability that we are here dealing with some form of doubly refracted ray of which one element is being received at each station. The direction of transmission makes an angle of 15° with the magnetic meridian, but owing to the high value of the magnetic dip in these latitudes it is difficult to link up these results with the theoretical formulæ. Further experiments on the subject are in progress.

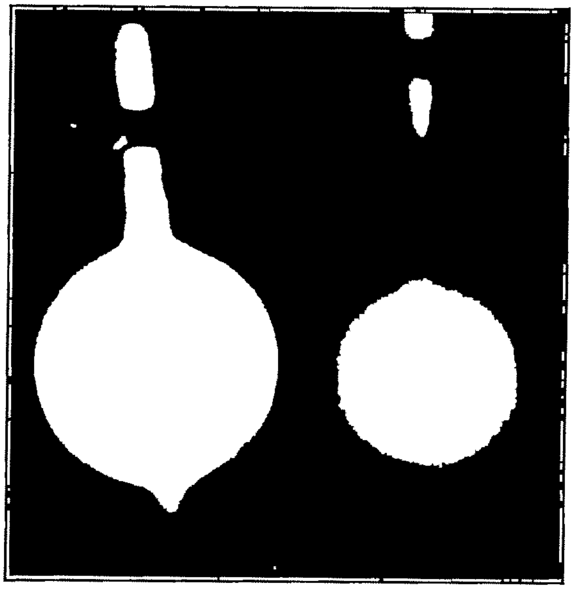
A New Form of the High Frequency Electric Discharge.

RECENTLY, we have conducted experiments on the electric discharge through gases at very low pressures with alternating potentials of about 4×10^7 cycles per sec. (7 metre wave). Results were obtained with mercury at pressures of the order of 10^{-3} mm. in a bulb 20 cm. diameter with neck of 2 cm. diameter, and external copper-foil wrappings as electrodes on the neck, and showed that the discharge could take two distinct forms as shown in the accompanying photographs.



A B

FIG. 1.

In the first type of discharge (Fig. 1, A) the discharge was projected as a visible streamer into the bulb below, which was almost completely filled with the glow. In the second case, with lower exciting power, the discharge (Fig. 1, B) took the form of a spherical glow of uniform luminosity separated from the walls by a dark space. A considerable portion of the neck of the bulb was completely dark, and discharges of the ball type could be maintained with no luminous effects at all in the side tube.

The behaviour of the two types of discharge when subjected to magnetic fields, showed quite diverse effects, and after many experiments with different gases, it was concluded that the bulb discharge was maintained (once initiated) by the stray alternating electric field from the electrodes which is projected down the neck into the bulb.

This new type of electric discharge is analogous to a uniform electron and positive ion high temperature enclosure, and preliminary results indicate that by its means many spectral and chemical problems may be attacked under conditions not previously realisable. The conditions of excitation are probably similar to those existing in the outer atmosphere of the sun.

JAMES TAYLOR.
WILFRID TAYLOR.

Subsidiary Rectangles as applied to the Formation of Magic Squares.

IN the issue of NATURE of Jan. 14 I gave the smallest 'associated' rectangle, consisting of 3 rows which has the property of the diagonals one way summing to the same as the rows. This was with non-consecutive numbers. The smallest associated rectangle with consecutive numbers is:

18	20	24	9	5	12	25	7	6
2	1	15	17	14	11	13	27	26
22	21	3	16	23	19	4	8	10

126 × 42

In this associated rectangle, the rows and the diagonals from left to right sum to 126, the columns to 42. But as with order 18 rectangles 6 × 3 the diagonal requirement is not necessary as associated pandiagonals with subsidiary rectangles 6 × 3 can be made otherwise.

This diagonal requirement is necessary for all associated pandiagonals with subsidiary rectangles of 3 rows, except as above, when the number of columns in the rectangle is a multiple of the number of rows (three), such as 6 × 3, 9 × 3, etc. With pandiagonals *not associated* consisting of subsidiary rectangles of 3 rows it is still necessary with all rectangles with an odd number of columns such as 7 × 3, 5 × 3, etc. I give an example of each:

14	17	15	12	4	9	6
1	3	2	11	21	19	20
18	13	16	10	8	5	7

77 × 33

14	12	11	2	1
6	9	8	7	10
4	3	5	15	13

40 × 24

These are with consecutive numbers and not associated. Rectangles with an even number of columns do not require the diagonals one way to sum to the same amount as the rows. Pandiagonal squares can be made by other methods. Such are 4 × 3, 8 × 3, etc.

Production of Bubbles of Selenium.

IT may be of interest to record that bubbles of selenium can be blown from the end of a suitably shaped glass tube, after dipping it momentarily into the molten 'metal.'

I find it best to use for this purpose a glass tube which has an internal diameter of about an eighth of an inch, and to bell out slightly the extremity which is to be dipped into the molten selenium.

The temperature of the selenium should be just below that at which it gives off a faint cloud of condensing vapour. By paying attention to these conditions, I have succeeded in blowing bubbles, usually somewhat irregular sausage-shaped things, as long as five centimetres, and three centimetres in diameter at the largest part.

The walls of these bubbles are extremely thin and show well the beautiful rich colour of selenium when viewed by transmitted light. The method also affords a simple means of obtaining small thin flakes of selenium for various experimental purposes.

Great care is required to regulate the air pressure, which only seems to be possible by blowing with the mouth. Success is obtained only by choosing the right moment when the selenium is so far cooled as to be highly viscous.

An interesting property of these bubbles is that if, even after twenty-four hours, they are brought into very light contact with one another, they seize violently together and cannot be again separated.

Inflammable Gas from Plants.

IN reply to Prof. Findlay's request in NATURE of Jan. 14, for information concerning the exhalation of an inflammable gas from the Fraxinella, I have much pleasure in communicating the following items:

(1) From page 336 of vol. 2 of "Chemical Essays," by Dr. R. Watson, Third Edition (London, 1784):

"*Fraxinella* is a very odorous plant; when in full blossom, the air which surrounds it in a still night may be inflamed by the approach of a lighted candle; does this inflammability proceed from an inflammable air, which is exhaled by the plant, or from some of the finer particles of the *oil* of the plant, being *dissolved* in the common air of the atmosphere."

(2) From page 107 of vol. 1 of "Elementary Lectures on Chemistry and Natural History." Translated from the French of M. Fourcroy (Edinburgh, 1785):

"The atmosphere which floats round the fraxinella is inflammable from the admixture of some essential oil: and M. Scheele is of opinion that every inflammable air is composed of a very subtile oil."

(3) From "Webster's New International Dictionary of the English Language" (London, 1919):

"Fraxinella. A perennial rutaceous herb (*Dictamnus albus*) with pinnate leaves and white flowers, which exhale an inflammable vapour in hot weather—often called 'gas plant.'"

'Self-Adaptation' in Biology.

"PARACELSUS, the first materialist, proclaimed man to be a chemical compound" (NATURE, Jan. 7, p. 14). No doubt Dr. Fournier d'Albe can give references to confirm this statement. In the meantime may I quote the following detached paragraphs?

"The life of man is an astral effluvium or a balsamic impression, a heavenly and invisible fire, an enclosed essence of spirit. . . ." ("De Natura Rerum," p. 81; Hartmann's "Paracelsus"). "Man has two spirits, a divine and a terrestrial spirit" ("De Lunaticis," *ibid.* p. 82). "Neither the external nor the astral man is the real man; the real man is the spiritual soul in connection with the divine spirit" ("De Fundamento Sapientiæ," *ibid.* p. 87). ". . . the organs of the body and the body itself are only form-manifestations of previously and universally existing mental states" ("De Viribus Membrorum," *ibid.* p. 219).

"Man is an instrument through which all the three worlds—the spiritual, the astral, and the elementary world—are acting. In him are beings from all these worlds, reasonable and unreasonable, intelligent and unintelligent creatures. A person without self-knowledge and self-control is made to act according to the will of these creatures" ("De Meteoris," *ibid.* p. 110).

Liquid Stars.

By J. H. Jeans, Sec. R.S.

The view that the stars are gaseous structures has held the field for more than half a century; it is implied in Helmholtz's famous 'contraction-theory' of the source of solar energy as well as in the pioneer researches of Homer Lane. Emden, surveying the subject in his "Gaskugeln," scarcely discussed any alternative possibility, although finding that the centres of the stars must be too dense for the ordinary gaseous state to be possible. This particular contradiction disappeared, and indeed the whole question assumed a new aspect, in the light of a concept I put forward in 1917, according to which the atoms in stellar interiors were in a state of extreme electronic dissociation. For, as Eddington afterwards pointed out, electrons and atomic nuclei are of such diminutive size that if these, and these alone, form the flying units of a quasi-gas, no density observed in astronomy is too high to be compatible with the gaseous state.

In the ten years which have elapsed since I first propounded this view of stellar interiors, much labour has been devoted, particularly by Eddington but also by many others, to investigating the build and properties of the stars on the hypothesis that the flying units are too small to interfere appreciably with one another's motion—on the assumption, in brief, that stellar matter behaves like a perfect gas. As the central temperatures of the stars can be calculated with some accuracy, it might seem a simple matter to estimate the extent to which these temperatures would break up the atoms, and thus to decide whether the gas-laws would be obeyed or not. It is simple if the atomic weight of the atoms is known, but not otherwise; a temperature of 100,000 degrees will break up hydrogen completely, while one of 100,000,000 degrees fails to do the same with uranium. Eddington's discussions usually assumed atomic weights of 40 or 50, and with such atomic weights the atoms would be completely pulverised; on the other hand, with atomic weights five times higher, enough atomic structure would be left to cause the gas-laws to fail, although our ignorance of the effective sizes of highly ionised atoms makes it difficult to estimate the extent of this failure.

The hypothesis that the gas-laws are obeyed has proved disappointing, its consequences obstinately refusing to fit observed facts, and the hypothesis appears to be ripe for abandonment. Eddington and myself have independently investigated the relation which would connect a star's luminosity with its mass and diameter on this hypothesis, and actual stars are all found to be substantially too faint. To put the same thing in another way, if the gas-laws were obeyed in stellar interiors, stellar diameters would be far greater than they actually are. My own latest calculations suggest that the discrepancy is probably represented by a factor of hundreds; Eddington, from different data and different assumptions, got a smaller factor, but even by giving the hypothesis all the benefits of every possible doubt, no one has succeeded in abolishing the discrepancy altogether; at the best a factor of about ten persists.

Further, I have recently shown that a star which behaved like a gas would be unstable, either dynamically or thermodynamically, or both. Some time ago Eddington and Russell found that such a star would be dynamically unstable unless its rate of generation of energy increased somewhat rapidly as its temperature rose, but I have since shown that an adequate effect of this kind would render the star unstable thermodynamically; to keep our star dynamically stable, we have to endow it with precisely those properties which characterise an explosive at its flash-point. Thus a purely gaseous star must collapse dynamically, or explode thermodynamically, or both, according to the way in which its rate of generation of energy depends on its temperature; actual stars do neither.

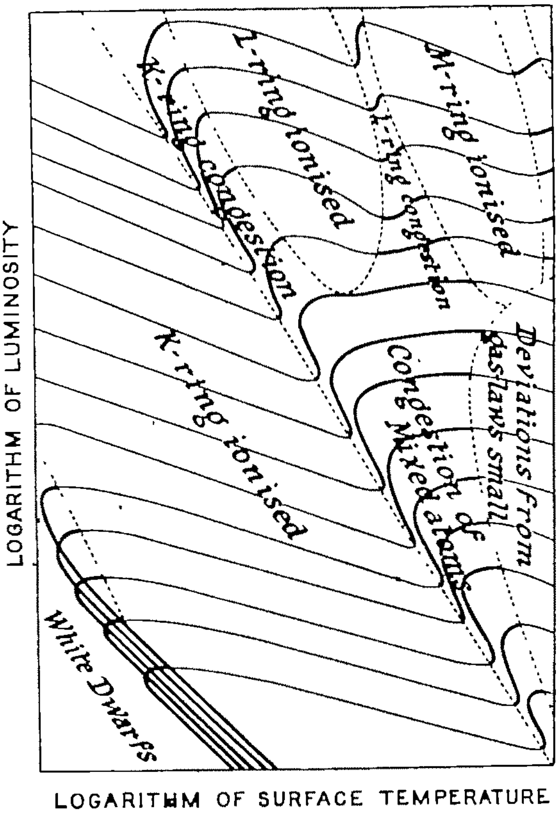

Fig. 1.—Theoretical diagram of stellar configurations predicted by the hypothesis of liquid stars.

Finally, direct evidence against the gaseous hypothesis is provided by binary stars which, to all appearances, have been formed by the break up of a single star which rotated too fast for safety. Flywheels and rotating masses of solid or liquid may break up in this way, but I have shown that a purely gaseous mass cannot; a mass of gas yields and expands, but can never break.

I have recently suggested (*Mon. Not. Roy. Ast. Soc.*, **87**, 400 and 720; 1927) that these various difficulties can be obviated, and a highly satisfactory agreement with observation secured, by supposing the central regions of a star to be liquid rather than gaseous, the outer layers of course remaining gaseous. In the quasi-liquid core the atoms are not completely broken up, retaining one, two, or even three rings of electrons, and as a consequence exerting about forty times the pressure they would if the gas-laws were obeyed. These deviations from the gas-laws secure the dynamical stability of the star, the nearly liquid core forming a firm unyielding base on which the outer layers of the star can rest in safety; thermodynamical stability is ensured by supposing the star's liberation of energy to be of the 'radioactive' type, so that it is approximately uninfluenced by changes of temperature and density.

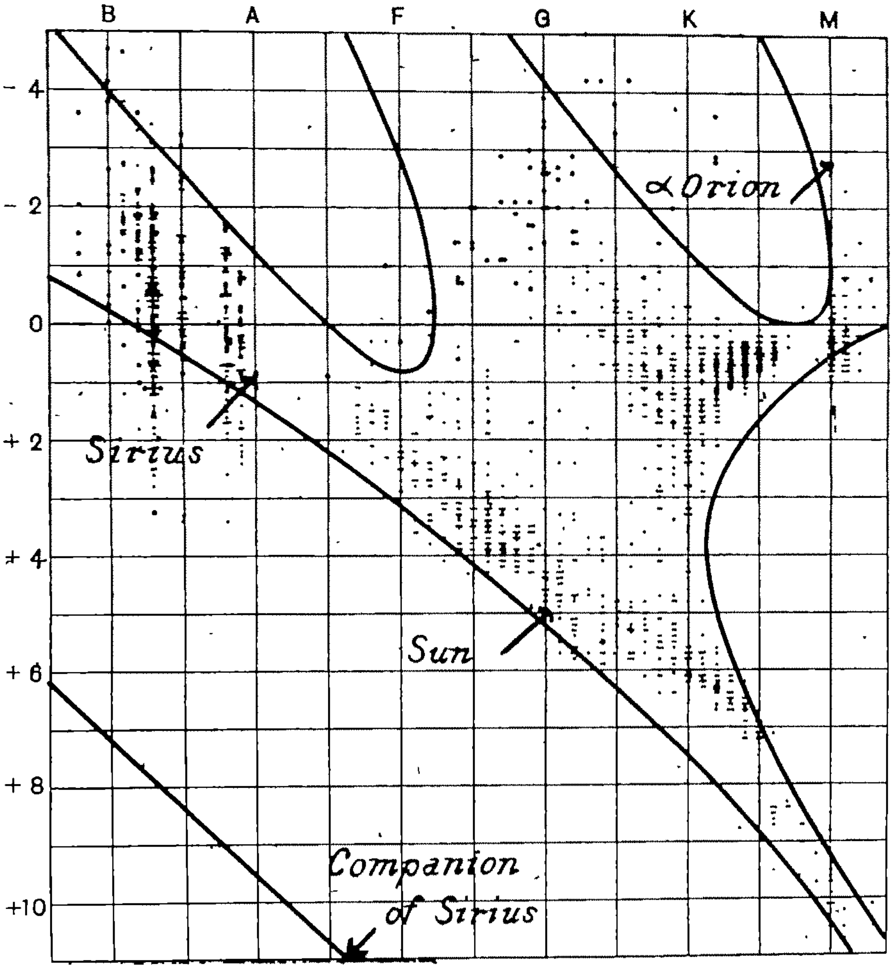

FIG. 1.—Diagram of observed stellar configurations (Mount Wilson Observatory).

Imagine a star starting from the low density with which it is born, and contracting through all its possible configurations of equilibrium. As its radius diminishes, its temperature rises as required by Lane's law, and this rise of temperature results in one ring of electrons after another being stripped from the atoms, so that the size of the atoms diminishes concurrently with that of the star. So long as the star is of low density, the gas laws are obeyed in its interior, but calculation shows that on the whole the star shrinks more rapidly than its atoms, so that in time states are reached in which the gas-laws are no longer obeyed. But while the star is shrinking steadily, its atoms shrink spasmodically as one ring of electrons after another is pulled off. If the stellar diameter is the tortoise, the atomic diameter is the hare; its progress is by spurts and rests alternately. The spurts of the hare do not save it from ultimate defeat, but they result in its being alternately in front of and behind the tortoise. Detailed calculation shows that, as the star shrinks, the deviations from the gas-laws will not increase steadily but will fluctuate, being small just after each ring of electrons has been ionised, and becoming large just before the ionisation of the next ring. At these latter stages the atoms are jammed together, a substantial degree of jamming generally being necessary to secure the ionisation of the next ring. Such, at least, are the predictions of theory for massive stars. In stars of small mass, the fluctuations are smoothed out and disappear; the hare goes with a steady gait, but is uniformly less rapid than the tortoise, at any rate until we come to the last ring of electrons, the k-ring. Here the hare makes a tremendous jump, and then has to stop since no further rings of electrons remain.

Fig. 1 shows the configurations which theory predicts to be possible for stars of different masses. The abscissa is the logarithm of the stars' surface-temperature, hot and therefore small stars being to the left; the stars' diameter increases to the right. The ordinate is the logarithm of the stars' luminosity, bright stars being on top. Each continuous curve represents the theoretically possible configurations for a star of given mass, the curves for the most massive stars being on top. The fluctuations in these curves result from fluctuations in the extent of deviation from the gas-laws, and these in turn entail fluctuations of stability. Theory requires that those parts of the curve which are drawn thick shall represent stable configurations, all others being unstable. Thus if the hypothesis of liquid stars is true, stars ought to be observed to occur only in those parts of the diagram where the curves are drawn thick.

The background of Fig. 2, taken from the Report of Mount Wilson Observatory (1921), shows the observed distribution of 2100 stars; the thick lines are curves I have drawn to divide the diagram into regions occupied by, and avoided by, stars. The general agreement with the theoretical diagram shown in Fig. 1 is so good that we need scarcely hesitate to identify corresponding areas in the two diagrams.

The belt of stars which runs diagonally across the whole diagram is called the 'main-sequence'; it contains stars of ordinary radius, such as the sun, Sirius, and Procyon. In the stars which occupy the upper reaches of the main-sequence we see that the atoms are ionised down to their *K*-rings, but the less luminous stars such as the sun must contain all sorts of atoms mixed. Observation shows that the left-hand edge of this sequence is very clearly defined; the stars seem to press against it like flies against a window-pane. This sharp left-hand edge is determined by the condition that the atoms are jammed together almost as tightly as they can be packed; in the configurations there represented the density is the maximum possible, short of the final ionisation of the *K*-ring. The "white-dwarfs," such as the companion of Sirius, with diameters only about a fiftieth of that of the sun, and densities of about a hundred thousand times that of water, consist mainly of atoms stripped bare to their nuclei, although enough *K*-rings must survive to build up a firm liquid base at the centre of the star. Stars of huge diameter, such as Betelgeuse (α Orionis), with diameters hundreds of times that of the sun, and mean densities only about a thousandth that of atmospheric air, must have three rings of electrons (*K*, *L*, *M*) left on their atoms.

The upper part of the diagram forms a macrocosm of the atom itself, the great difference between the diameters of the nucleus and the k-ring being reflected particularly clearly in the big empty gulf between the white-dwarfs and the main-sequence. Thus the structure of the atom is blazoned across the heavens, and if the physicists had failed to unravel it, the astronomers might have succeeded—in time. Theory does not fix absolute values for the co-ordinates in Fig. 1 until the atomic weights and atomic numbers of the atoms are given. I have found that the best agreement with the observational material shown in Fig. 2 is secured by taking the atomic number to be about 94. Atoms of lower atomic number would lose their electrons at too low temperatures, while those of higher atomic numbers would grip them too tightly. Thus the main mass of the central liquid regions of the stars appears to consist of a sort of "supra-radioactive" atoms, with atomic numbers just above those of the ordinary radioactive elements such as radium (88) and uranium (92). We are driven back to Newton's conception of the stars as being formed of a special 'lucid' type of matter, and this lucid matter appears to come next in complexity after our terrestrial semi-lucid radioactive elements, of which the lucid elements may well be the parents.

Power Alcohol in Australia.

By Prof. JOHN READ.

THE main sources of organic energy which are at present being utilised in Australia are black coal and brown coal. The Australian deposits of black coal form about 2·2 per cent. of the total coal reserves of the world, being thus only slightly less extensive than the deposits of Great Britain. The chief deposits of black and brown coal occupy very favourable locations in New South Wales and Victoria, respectively; and, in addition, the eastern coastal zone of Australia (including Tasmania) affords considerable opportunities for the development of hydro-electric power. In comparison with Great Britain, therefore, Australia is well endowed with natural sources of energy. At present, however, both these countries are almost wholly dependent upon outside sources for their supplies of liquid fuels, particularly for fuels fulfilling the requirements of the internal combustion engine. A very similar state of affairs exists in South Africa and in various other parts of the Empire; so that a problem of wide significance and extreme economic importance is here manifest.

In Great Britain, as in Europe generally, a good deal of attention is being paid to the Bergius process and the low temperature distillation of coal. Any such investigations directed towards the economic manufacture of liquid fuels from black or brown coal are patently of considerable interest to Australia, particularly as the processes would also furnish lubricating oils. Climatically, however, Australia differs so widely from Great Britain and northern Europe that it is not surprising to find the Australian more disposed than the European to draw upon his lavish current supplies of solar energy and less inclined to encroach unduly upon his limited capital of 'fossil sunshine.' This tendency is noticeable in a report issued recently by the Council for Scientific and Industrial Research of the Commonwealth of Australia, entitled "The Possibilities of Power Alcohol and certain other Fuels in Australia" (*Bulletin* No. 33. By G. A. Cook. Melbourne, 1927). The Australian imports of petrol and other petroleum products are increasing rapidly, the value of imported petrol alone being more than £6,500,000 per annum at the present time. Such a position is characterised as "very unsatisfactory even in times of peace, but in times of emergency it becomes positively dangerous." In 1925, the Joint Parliamentary Committee on Public Accounts took evidence on all phases of the Australian liquid fuel problem, and came to the conclusion that "the consensus of geological opinion concerning the prospects of flow oil being discovered in commercial quantities in Australia is unfortunately not very favorable." Apart from oils obtainable from coal and shale, power alcohol and related synthetic fuels are recognised in the report under notice as the most likely substitutes for natural petroleum in Australia.

In reviewing possible Australian sources of power alcohol, it is pointed out that the starch-producing cereals are in general too important as foodstuffs to be utilised for other purposes; but in some Australian localities "the fermentation of certain varieties of tubers is by no means commercially unattractive even under present conditions and prices. Cassava, arrowroot, the sweet potato in the warmer climates, and perhaps beet in the milder, are at least worth consideration in this connexion. Some sugar-producing grasses, for example, sorghum, also have prospects." The nipa palm, which has been stated to provide a better source of sugar even than the sugar-cane, is a further raw material of considerable interest, since it grows abundantly in certain regions of Papua and the mandated territory of New Guinea.

Owing to the bulky nature of the raw materials, the conclusion is reached that at present it would be possible at the best to establish distilleries in favoured localities where the production of suitable high-grade materials presents no particular difficulty. In such districts imported petrol might be largely replaced by alcohol, but it appears that a complete replacement is incapable of achievement in the absence of a successful method for producing liquid fuels from raw celluloses. "From the point of view of the producer of power alcohol, Australia may be considered to be a favoured field of operation. . . . On the one hand, the local price of petrol is high, and on the other an ample and cheap supply of cellulosic raw materials is available. In view of the possibilities of ultimate success, and in view of the urgent national need, the chemists and bacteriologists of Australia might well cooperate and interest themselves in the problem, the former to develop the most suitable methods of producing large quantities of fermentable materials per ton of cellulose, and the latter to discover the organisms best suited for the subsequent fermentation."

As regards synthetic methods for the production of power alcohol, neither ethylene nor acetylene is held to offer promise as the basis of a satisfactory commercial process in Australia; but a comparison of the prices of petrol in the countries concerned makes it conceivable that some other synthetic process might be capable of successful operation in Australia although perhaps economically impracticable in Europe or the United States.

Technologically, the best raw material available in Australia for manufacturing power alcohol is molasses. In the record season of 1925–26, the total production of crude sugar in Australia exceeded 500,000 tons; of the accompanying 120,000 tons of molasses, however, a large proportion was either used as fuel, cattle food, etc., or wasted. If utilised wholly in the manufacture of power alcohol, this by-product would yield only about one-twentieth (7,800,000 gallons) of the current Australian demand for motor fuels.

The Australian investigations on power alcohol include experiments on the cultivation of sorghum, artichokes, sugar beet, cassava, sweet potatoes, arrowroot, etc.; the preparation of alcohol from the carbohydrates of zamia palms, grass-tree cores, and prickly pear; the hydrolysis and fermentation of common Australian hardwoods (NATURE, Oct. 8, 1927, p. 522); and the use of alcohol as an engine fuel under various conditions. Coming to actual commercial achievement, a power alcohol distillery with a capacity of about one million gallons per annum started production in February 1927, at the Plane Creek sugar mill, near Mackay, Queensland. The raw materials are molasses and certain starchy crops, including cassava and arrowroot. The fuel, consisting essentially of a mixture of alcohol and ether, is marketed under the name of 'powrac.' As an extension of this enterprise it is proposed to erect other distilleries in the Cairns district of Queensland.

Obituary.

PROF. C. DIENER.

CARL DIENER, who died in Vienna on Jan. 6, was born in that city on Dec. 11, 1862, there received the whole of his formal education, and there ran his professional career. As a student there was no need for him to go elsewhere, since he had as teachers some of the most eminent men of the age: in geography, F. Simonyi; in geology, E. Suess; and in palæontology, M. Neumayr. But when he had finished his student course in 1883, he at once turned for a wider experience to mountaineering in the Alps, in Dauphiné, and in the Pyrenees. He was among the first to introduce Alpine climbing into Austria itself, and was for seven years president of the Austrian Alpine Club; his membership of the English Alpine Club was, to his deep regret, broken by the War.

Naturally Diener did not leave his scientific interests behind when he sought the high mountains, and on the results he obtained in the Lebanon, Antilebanon, and the region of Palmyra, he habilitated as privat-docent for geography so early as 1886. Geology, however, claimed more and more of his attention, and the turning point of his career came when in 1892 he joined an expedition financed by the Government of India and the Vienna Academy, to examine the Trias of the Central Himalayas. In the first place, the valuable geological results obtained led him to extend his teaching to geology in 1893, and caused him in 1897 to be nominated professor extraordinarius of that science. Secondly, he was associated on the expedition with Griesbach and Middlemiss of the Indian Geological Survey, and this led to an intimate connexion that ceased only with the War. Thirdly, the rich collections of fossils made by the expedition inevitably involved him more and more in palæontology. Thus in 1903 he became professor extraordinarius, and in 1906 was appointed full professor of palæontology and holder of that chair in the University of Vienna. His academic progress was fitly rounded off by his election as Dean of the philosophical faculty for 1919–20, and as Rector of the University for 1922–23.

Thus, for all his geographical interests and tectonic surveys, it is mainly as a palæontologist that we know and honour Diener. Englishmen are most familiar with the twelve magnificent monographs on Himalayan fossils which he contributed to *Palæontologica Indica* from 1895 to 1915. His most distinctive work in this line was on the Triassic Cephalopoda, where, on the death of Mojsisovics in 1907, he succeeded to the prime authority. The material for his Triassic studies came not only from the neighbouring Alps and the Himalayas, but also from Madagascar, Timor, Tonkin, Siberia, and Japan. His masterly summary, "Die marinen Reiche des Trias Periode" (1915), embodied the results of this work and of his extensive travels to many of the famous Trias exposures of the world. Would that he had given us an equally good summary of his knowledge of the Triassic cephalopods! From this, in his Catalogue (1915), he intentionally refrained, holding that the state of ammonite classification did not permit of it.

As palæontologist Diener was no mere describer, but interested himself in such subjects as the mode of life and distribution of the ammonites, the phenomena of convergence, and more generally in all those relations of fossil faunas to the rocks in which they occur that make up the division of palæontology now known as biostratigraphy. Indeed his "Grundzüge der Biostratigraphie," published in 1925, forms a conspectus of the subject no less admirable for clarity and sanity of treatment than for the wide learning on which it is based. The preparation of this work occupied him during the later years of public distress and of personal suffering from the internal disease to which he has at last succumbed.

Diener had a quiet but attractive personality, and his clear elocution and interesting subject matter made his lectures peculiarly inspiring. He was a member of the Vienna Academy and the recipient of many honours from other learned bodies. In 1913 he was made a corresponding member of the British Association. The Geological Society of London elected him foreign correspondent in 1912 and foreign member in 1926, an honour which he valued highly as a recognition of his long-continued work for the geology of the British Empire. F. A. B.

MR. E. R. WAITE.

THE death is announced of Edgar Ravenswood Waite at Hobart, Tasmania, during the nineteenth meeting of the Australasian Association for the Advancement of Science. Mr. Waite was born at Leeds in 1866, and at an early age took a keen interest in natural science; he was eventually appointed curator of the Leeds Philosophical Society, and was joint author with the late W. D. Roebuck of a work on "The Vertebrate Fauna of Yorkshire." He took an active part in the organisation of the Yorkshire Naturalists' Union, and at one time was joint-editor of its well-known organ the *Naturalist*. In 1892 Mr. Waite was appointed zoologist to the Australian Museum, and shortly afterwards accepted the appointment of Curator to the Canterbury Museum, New Zealand. Afterwards he accepted the directorship of the Government Museum at Adelaide, South Australia. Two years ago he returned to Europe, and after seeing the various museums on the continent and America, he visited his native place at Leeds, and was entertained there by many of his former colleagues.

Mr. Waite specialised in the study of mammalia and fishes, and took several expeditions to the Antarctic, where to-day a mountain bears his name. He described the fishes taken on the Shackleton and Mawson Expeditions, and is the author of the standard work dealing with the snakes of Australia. During the War he did good work by visiting various territories in the Pacific. He also collected extensively in the New Ireland and New Britain areas, and his Museum is considerably richer as a result of his work.

Mr. Waite's early experience as editor of the *Naturalist* and in other ways resulted in his being a prolific writer, and more than a hundred monographs and papers are to his credit. T. S.

WE regret to announce the following deaths:

Prof. José Rodriguez Carracido, for many years Rector of the University of Madrid, who worked chiefly on the action of alkaloids upon organisms and was the author of several text-books on biochemistry, aged seventy-two years.

Mr. J. H. Durrant, who was associated for many years with the late Lord Walsingham's collection of Microlepidoptera at Merton Hall, Norfolk, and afterwards at the British Museum (Natural History), on Jan. 20, aged sixty-five years.

Dr. Harry N. Gardiner, emeritus professor of philosophy at Smith College and president in 1907 of the American Philosophical Association, on Dec. 20, aged seventy-two years.

Prof. R. W. Genese, professor of mathematics in the University College of Wales, Aberystwyth, from 1879 until 1919, on Jan. 21, aged seventy-nine years.

Major-General G. W. Goethals, chief engineer for the construction of the Panama Canal and first civil governor of the Canal Zone, on Jan. 21, aged sixty-nine years.

Mr. M. Longridge, C.B.E., president in 1917 of the Institution of Mechanical Engineers, on Jan. 18, aged eighty years.

Count Meredyth de Miremont, author of well-known star charts and of "Practical Methods in Modern Navigation," on Jan. 21.

Dr. George Muirhead, author of "Birds of Berwickshire" and other works on Scottish natural history on Jan. 29, aged eighty-two years.

Mr. P. D. Warren, C.M.G., formerly Surveyor-General of Ceylon, on Jan. 28, aged seventy-six years.

News and Views.

It was announced last week that Lord Bledisloe is resigning his post as Parliamentary Secretary to the Ministry of Agriculture to take up the appointment of chairman of the Imperial Grassland Association, which is being formed under the auspices of Imperial Chemical Industries, Ltd., with the object of improving the pasture land of Great Britain and of the Overseas Empire. Lord Bledisloe has rightly earned a great reputation as one who has taken the keenest interest in all phases of agriculture and has devoted so much of his energies to the furtherance of its well-being. Whilst his loss to the Government will be keenly felt, his new position will offer plenty of scope for his great enthusiasm and his wide experience of agricultural matters. The formation of the Imperial Grassland Association, further details of which will be awaited with great interest, is a further step in the developments which have been fostered in recent years by Imperial Chemical Industries, Ltd., through their associated companies, Synthetic Ammonia and Nitrates, Ltd., and Nitram, Ltd. The former company, at its great works at Billingham-on-Tees, now possesses plant with a total output capacity of fixed nitrogen equivalent to about 1000 tons of ammonium sulphate per day, and further big extensions are planned involving the production of a wide range of fertilisers. Nitram, Ltd., besides being responsible for the sale of the ammonium sulphate and other fertilisers produced at Billingham, as well as for most of the by-product ammonium sulphate produced in Great Britain, has recently established an agricultural research and advisory department, under the directorship of Sir Frederick Keeble, and with a strong scientific staff and well-equipped laboratories and experimental farm.

One of the chief directions in which the activities of Nitram, Ltd., have been exercised is in the development of the intensive system of grassland management. This system aims at greatly increasing the productivity of grassland by the application of a complete manure, including nitrogen. Trials have been carried out all over England during the past two years, with most encouraging results. The stock-carrying capacity of pasture land has been doubled or trebled, with a proportionate increase in the milk production per acre. Thus, in one trial the milk produced during the grazing period, from treated pasture, was raised to 713 gallons per acre, which is equivalent in food value to the production of arable land giving a yield of 4½ quarters of wheat per acre. Hitherto the stock farmer has been dependent for a large proportion of the protein in his feeding stuffs on imported concentrates (oilcakes). The price of nitrogen in this form, always high, is now much higher than before the War. Nitrogen in the form of artificial fertilisers, on the other hand, is now actually cheaper than before the War. The new system of grassland management, therefore, holds out to the farmer the possibility of using this cheap nitrogen for the production on his own land of a large proportion of the protein food needed for his stock, and that in the ideal form, as young grass. Moreover, the money paid for that nitrogen remains in the country, instead of going abroad in payment of imported concentrates. Much has still to be done in working out the details and the economics of this system, both in Great Britain, already famous for the quality of its grassland, and in the Overseas Empire, in many parts of which, as for example in New Zealand, grassland husbandry is a major industry, but the prospects are encouraging. The modern developments of the synthetic fertiliser industry make it abundantly clear that the manufacturer and the farmer are united by a common bond of interest in promoting the prosperity of the agriculture of the British Empire both at home and overseas. This bond is notably strengthened by the association of an agriculturist of the eminence of Lord Bledisloe with the great industrial interests represented by Imperial Chemical Industries, Ltd.

Sir James Walker, whose impending retirement from the chair of chemistry in the University of Edinburgh is announced elsewhere in this issue, received his early training in chemistry in Edinburgh under Crum-Brown and at Leipzig under Ostwald. He also carried out research work at Dundee with Carnelley, and then went to University College, London, as an assistant to Sir William Ramsay. In 1894 he was appointed professor of chemistry at University College, Dundee, and in 1908 was appointed to succeed Prof. Crum-Brown at Edinburgh. Sir James has been an indefatigable worker. While his name will always be associated with the development of physical chemistry, his work has covered a great range of subjects—the theory of solution, hydrolysis, the theory of amphoteric electrolytes and the electrolytic synthesis of organic acids, to mention only a few of the problems at which he has worked. As an author of chemical text-books he is equally well known. His "Introduction to Physical Chemistry," originally published in 1899, now in its tenth edition, is still widely used in both Great Britain and the United States; amongst his other text-books may be mentioned his "Organic Chemistry for Students of Medicine," and a most useful introductory work on "Inorganic Chemistry."

During the War Sir James Walker rendered valuable services by erecting and equipping, in conjunction with some of his colleagues in the Chemistry Department of the University of Edinburgh, a factory—acknowledged to be a model of its kind—for the manufacture of T.N.T., which produced this explosive at an exceedingly economical rate. After the War the increase in the number of students and the development of the science made it necessary for the University to undertake the erection of the new chemical laboratories. Sir James had the principal share in the conception and execution of this project, which has resulted in the possession by the University of a Department of Chemistry at King's Buildings which is unrivalled in Britain. The foundation stone of the Department was laid by His Majesty the King in 1920, and it was opened on completion in 1924 by the Prince of Wales. In addition to his teaching and research work, Sir James has been an active member of the various learned societies connected with his subject. He is a fellow of the Royal Society and is at present serving on its Council. He was president of the Chemical Society (1921–23), and in 1913, at the invitation of the Council, delivered the Van 't Hoff Memorial Lecture. He received the degree of LL.D. from the University of St. Andrews in 1895 and was knighted in 1921.

A THOROUGH trial of geophysical prospecting methods will be carried out in Australia during 1928 and 1929 under an agreement concluded between the Commonwealth Government and the Empire Marketing Board. The Australian arrangements will be in the hands of the Council for Scientific and Industrial Research and the Development and Migration Commission. Mr. Broughton Edge will be in charge of the survey party and, with two of the assistants who have been with him in Rhodesia, will commence his work next March. The rest of the staff will probably be Australian, and will include a gravimetrist, an electrician, two surveyors, and a laboratory assistant. A suggestion that the Department of Scientific and Industrial Research should appoint a physicist to accompany the party has been cordially welcomed in Australia. In order that the best available information may be placed at the disposal of Mr. Edge, a conference is being arranged of the heads of State Departments of Mines, Geological Surveys, and Physics Departments of the universities to discuss the general position, and particularly the question of the most suitable localities for the tests. Later, a smaller body will be constituted to ensure intimate touch with State Government organisations during the progress of the work.

AT a meeting of the Surveyors' Institution on Monday, Jan. 9, Mr. C. H. Bailey read a paper on "The Reports of the Royal Commission on Mining Subsidence." In the printed version available he gives a summary of the position and main recommendations contained in the Final Report of the Commission by way of an appendix, whilst his paper was devoted to a discussion of these points. Upon the whole, Mr. Bailey has dealt very fairly with the Report of the Commission, except for the fact that he does not seem to have borne in mind the exact terms of reference. Thus he states that "the questions which are discussed by the Commissioners are these: (1) Can damage due to subsidence be prevented or lessened? (2) Does the existing law bear unfairly on any section of the community?" In actual fact it is only the latter of these two questions which was, strictly speaking, before the Commission, the terms of reference being "To consider the operation of the law relating to the support of the surface of the land . . . and to report what steps should be taken, by legislation or otherwise, to remedy equitably to all persons concerned any defects or hardships that may be found to arise in existing conditions."

THE first of Mr. Bailey's questions was only discussed incidentally by the Commission, and therefore no recommendations are made with respect to it. The main recommendation of the Commission referred to small house property, and Mr. Bailey states it in the following terms: "The proposal to restore the right to support or compensation to houses of £40 or less rateable value." This statement involves a somewhat serious error; the Commissioners definitely do not attempt to restore the right to support (where this for any reason has been lost); they limit their recommendation to compensation, and the reason for this limitation is very clearly and fully stated in the Report of the Commission itself, in which it is pointed out that the legal position has been profoundly modified by the Mines (Working Facilities and Support) Act, 1923, which enacts that when property entitled to support is injured, the owner is entitled to pecuniary compensation, but must be content with such compensation, and in view of the very definite terms of the Act the Commission could not attempt to restore any right of support, but could and would only recommend means for awarding pecuniary compensation. The point is rather an important one, but apart from this it may be said that Mr. Bailey's review of the Commission's Report is a very reasonable one.

ORDINARY telegraph lines are often seriously affected by auroræ, storms, and floods. A novel way of overcoming these difficulties has been successfully tried in Canada. The offices of the Canadian National Railways at Montreal and Winnipeg, a distance of 1300 miles, are now in direct telephonic communication with one another. Before the line was installed, calls from Winnipeg had to go by Chicago and St. Paul. The telephone messages are transmitted over the same wires that convey telegraph messages in the Morse code, the carrier current system familiar to radio engineers being employed. The telegraph and telephone messages can be sent simultaneously, there being no interference. At the receiving end of the line the messages are sorted out by special apparatus, each tuned to a particular frequency. The telephone messages are practically unaffected by electrical storms which throw the older telegraph services out of commission. Experience has shown that earth currents have no effect whatever on the service. Poles and wires may be submerged without affecting the transmission. Even when one of the wires was cut, it was still possible to work the line successfully.

THE nomenclature of disease has at present no principles. Since it was delimited from other vague fevers by the discovery of its causative agent, the fever which prevails round the Mediterranean, and is caused by the *Micrococcus melitensis*, has generally been known as 'Malta fever.' The inhabitants of Malta think that this association is prejudicial to their moral and material interests, and want the term 'undulant fever' substituted. Surely they should rather be proud that their island was the scene of one of the best pieces of modern work in bacteriology and hygiene. They would do better to devote their energy to commemorating the name of Sir David

Bruce by placing the causative organism in the genus Brucella instead of Micrococcus, and in dealing so effectively with their goats (which are the reservoir from which human infections are derived) that the island stands out as the one place where the fever cannot possibly be caught. At present 'Malta fever' is obviously the appropriate name for a disease due to a *melitensis* microbe: to change it would do no good and only create confusion. About the right name of the organism there is fortunately no doubt: *melitensis* is its first and only title.

IN the Friday evening discourse delivered at the Royal Institution on Jan. 27 on "Prehistoric Cave Art," Miss D. A. E. Garrod stated that although remains of Upper Palæolithic man are found all over Europe, the artistic impulse which gave rise to the animal paintings of the caves appears to be a local development, practically confined to central and southern France and northern Spain, the three chief centres being the Dordogne, the Pyrenees, and the Cantabric region. Cave art takes the form of painting, engraving, and sculpture. Owing to the fact that the paintings and engravings are often superimposed, it has been possible to work out their relative ages, and to establish a series showing a more or less continuous development from simple outlines, through monochrome shading, to the great polychromes which reach their zenith in the cave of Altamira. Remarkable sculptures in high relief are found in the rock-shelter of Cap Blanc near Les Eyzies, buried in deposits of early Magdalenian age, while in two Pyrenean caves which have been rendered nearly inaccessible by running water, clay models of animals have been preserved. It is clear from internal evidence that the art of the caves was inspired by a double purpose. In some cases it was directed to the promotion of fertility in the animals on whom man depended for his food; in others to ensuring good luck in the chase.

PROF. S. LANGDON'S report on the work of the Oxford-Field expedition's excavations during the current season at Kish, in his letter to the *Times* of Jan. 28, is of greater interest in its general bearing than for the actual finds recorded. The expedition is now bringing to light from the lowest levels of this city, which tradition says was the first capital of Sumer after the Flood, similar painted pottery and pictographic tablets to those found at Jemdet Nasr, 17 miles to the north-west. The civilisation of the two sites is not that of Sumer; both the pictographic script and the system of numeration are different. The painted pottery also differs from the painted ware of the southern area, that is, Sumer proper; but it is related to that of early Elam. Some of the pictographs are strikingly like those of the seals from Harappa and Mohenjo-Daro in India. This script is one of a group of five independent scripts belonging to the same prehistoric civilisation which spread over Asia from China to the Mediterranean before 4000 B.C., the other members of the group being Sumerian, proto-Elamite, Indus Valley, and early Chinese. The existence of a new branch of this homogeneous culture characterised by monochrome and polychrome ware in the region of Central Mesopotamia, between Babylon and the Tigris, is, Prof. Langdon points out, a new factor in ancient history. The discovery by the expedition of good Sumerian tablets at levels dated at 3500 B.C. proves that this culture ceased to exist at Kish before that date. Numerous seals and shell plaques also testify to the Sumerian occupation after its disappearance.

MUCH ingenuity has recently been expended in devising a code which would enable any listener anywhere to identify at once the broadcasting station to which he may be listening. Amongst the suggestions are various ways of sending morse signals by bells, hooters, and trumpets. In an article in the *Wireless World* for Jan. 11, Captain Eckersley points out that the vast majority of listeners to broadcasting have no interest in trying to identify the distant broadcasting station, the attenuated waves from which produce a curious noise in a multivalve receiving set. It would be foolish to handicap every item of a performance by a discordant signal merely to enable a few researchers to identify a particular noise. If it is essential that they satisfy their curiosity, then they should use a wavemeter, and look up a list of stations. It is difficult to see what useful purpose is served by identifying a very weak signal received on a large multi-valve set. The ether is full of strange noises, but those due to natural phenomena are of the greatest importance to physicists, and we are only slowly learning how to identify them. Excellent work is being done at the present time in attempting to link up European broadcasting stations to Great Britain by land telephone cables. In this way the local station can radiate the performances taking place abroad, the announcer telling what we are to hear and where it comes from. We look forward to hearing in this way in London an opera in Vienna or a German orchestra in Berlin. Direct listening to foreign and distant stations, whether identified or not, is rarely pleasurable. It is probable that, in the future, by utilising short wave transmissions, broadcasting programmes from any part of the world will be radiated with but little distortion from many local stations.

IN the construction of the Scottish section of the British national 'grid' of electric overhead wires, steel cored aluminium conductors are being used. Some engineers have expressed doubts as to the permanence of the qualities of these composite conductors. It is satisfactory, therefore, to read a paper by E. T. Painton in the *Electrician* for Jan. 27 giving both experimental and practical results on these wires extending over a period of years. It is known that pure aluminium does not corrode even in the neighbourhood of cement works. On the other hand, aluminium is strongly electro-positive, and unless a junction can be kept perfectly dry, it should not be used in contact with other metals. We might expect that the natural tendency of steel to rust would be increased in the case of composite wires by electrolytic action. Practical experience, however, has proved that over long periods of operation no case of corrosion has occurred. In order to test whether a single layer of aluminium wires was sufficient to protect the galvanised steel core, Mr. Painton erected steel cored aluminium wires along the sea wall of a harbour in Northern Ireland. On stormy days the wires are wet with sea water and subjected to the penetrating action of the wind. Every six months short lengths of the wires were cut off and their mechanical and electrical properties were measured and their appearance noted. After five years, there has been no diminution in the strength of the aluminium strands, and although the galvanising of the core is no longer bright, there is no sign of rust. The galvanising still withstood three full minute immersions in copper sulphate. These results are important, as steel cored aluminium is 80 per cent. stronger mechanically than the equivalent copper cable. The huge State network in France, which forms an important section for the rehabilitation of the devastated areas, consists almost entirely of steel cored aluminium wires.

The use of electricity for baking ovens was discussed by E. Styles in a paper read to the Institution of Electrical Engineers on Jan. 19. In Great Britain very little progress has been made in the application of electric heating to bakers' ovens. This is generally attributed to the high cost of electrical energy. But the author showed that the cost of the energy is only about three per cent. of the price of the bread when energy can be obtained at ½*d*. per unit. The oven can be heated very quickly by electric current, and it can retain its heat for many hours after the current has been switched off. As baking is generally carried out during the night, most electric supply companies would allow special rates for these ovens. When an electric oven is used, there is a considerable saving of floor space and of labour, as dirt and ashes are eliminated and no cleaning of flues is necessary. Owing to the ease with which the temperature can be maintained constant, there is an appreciable saving in the quantity of ingredients used. On the Continent and in the United States, the number of bakeries which heat electrically is rapidly increasing. In several towns in Great Britain they could be installed economically at the present time.

A recent addition to the Department of Zoology of the British Museum (Natural History) is a mounted specimen of a young Sumatran rhinoceros, presented by His Highness the Sultan of Perak; the specimen is of exceptional interest as exhibiting the very hairy nature of the skin in the young of this species. The Department has also acquired the skin and skeleton of a gorilla collected for the Museum in the Belgian Congo, by special permission of the Belgian Minister for the Colonies. Through the generosity of Sir George H. Kenrick, the series of types contained in the Museum has received a valuable addition in the shape of 218 specimens, of which 197 are types, of New Guinea and Madagascar butterflies and moths. This donation comprises the types of 21 species of butterflies and 176 species of moths, many of which were described by Sir George Kenrick himself, and also the Malagasy Geometridæ described by Mr. L. B. Prout.

Among recent purchases for the Geological Department the most interesting is a curious fossil from the lithographic stone of Solnhofen in Bavaria. It looks like two pieces of a large curved feather, and is thought to be a colony of hydroid polyps related to the modern Sea Fir. This fragment was no doubt torn up by a storm from a neighbouring sea-floor and swept on to the flats of the Solnhofen lagoon at the time when Kimmeridge Clay of Britain was being laid down. A small lot of fossils recently obtained from the London Clay included the shell of a Pinna in which were several pearls. Recent donations include the pupa-case of a dragon-fly found by Mr. W. H. Wickes in the Rhætic plant bed near Bristol; 147 shells from the Cretaceous and Pliocene rocks of Angola, collected by Mr. Beeby Thompson; five bony fishes from the Eocene of Egypt, including a new sole and a new form of primitive eel, discovered by Mr. C. Crawley. The total number of visitors to the Museum during 1927 was 569,318, and constitutes a record. The highest attendance in any previous year was 535,116 in 1909. The number of visitors on August Bank Holiday, 13,431, while not quite the largest recorded on any one day, is in striking contrast with the number, 506, on Boxing Day. These figures illustrate the effect on museum attendances of two different types of bad bank-holiday weather.

Dr. C. G. Abbot, who is well known for his work on the measurement of the solar constant, has been elected secretary of the Smithsonian Institution of Washington.

The annual meeting of the Iron and Steel Institute will be held on May 3–4, at the house of the Institution of Civil Engineers, Great George Street, London, S.W.1, under the presidency of Mr. Benjamin Talbot. The autumn meeting of the Institute will be at Bilbao during the week commencing Sept. 24.

The Geological Society of Stockholm has elected the following to corresponding membership: Dr. F. A. Bather, London; Prof. Reginald Daly, Cambridge, Mass.; Prof. P. Niggli, Zurich; Prof. Charles Schuchert, New Haven, Conn.; Dr. E. O. Ulrich, Washington.

The Ministry of Health has issued "Amendment Regulations" dealing with the labelling of condensed and of dried milks. They are primarily designed to secure that in the labelling of condensed and dried skimmed milks, greater prominence shall be given to the words "Unfit for Babies." These Regulations are to come into force in May and in September 1928, respectively.

Owing to the occurrence of a number of cases of smallpox among casuals during recent weeks, the Minister of Health has directed that from now until Mar. 31 next, the medical officers of all Unions shall examine all casuals admitted, with the view of detecting cases of smallpox (Circular 859).

Several letters on sun images through window glass, referring to Prof. S. Russ's letter in our issue of Jan. 14, have been received, which record similar observations. It seems probable that the formation of these images is due to parts of the glass having an appreciable convexity, which cannot, however, be detected by the naked eye.

At the anniversary meeting of the Royal Anthropological Institute, held on Jan. 24, Prof. J. L. Myres was elected president in succession to Mr. H. J. E. Peake, whose term of office has expired. The vacancy for a vice-president was filled by the election of Prof. H. J. E. Fleure, and Mr. G. D. Hornblower was elected to the office of honorary treasurer in succession to Dr. F. C. Shrubsall, who has resigned on account of pressure of other work.

The twentieth annual general meeting of the Institute of Metals will be held in London on Mar. 7 and 8, under the presidency of Dr. W. Rosenhain, Superintendent of the Department of Metallurgy and Metallurgical Chemistry in the National Physical Laboratory. The papers to be read and discussed include contributions from metallurgists in Germany, Japan, and the United States, as well as Great Britain. The autumn meeting will be held at Liverpool on Sept. 4 to 7.

It is announced in *Science* that the Edison medal, conferred annually by a committee of the American Institute of Electrical Engineers for "meritorious achievement in electrical science, electrical engineering, or the electrical arts," has been awarded for the year 1927 to Dr. William D. Coolidge, assistant director of the research laboratory of the General Electric Company, "for his contributions to the incandescent electric lighting and to the X-ray arts."

The ninetieth meeting of the German Society of Naturalists and Physicians will be held at Hamburg on Sept. 16–28 next. Special emphasis will be given in the general meetings and in the sections to the relationship of German science and medicine to maritime studies and to overseas countries. Particulars of the meeting can be obtained from Prof. B. Rassow, Geschäftsstelle der Gesellschaft Deutscher Naturforscher und Ärzte, Leipzig C.1, Gustav-Adolf-Str. 12.

The Registrar-General has issued the provisional figures for England and Wales of the birth-rate, death-rate, and infantile mortality during the year 1927. The birth-rate and the death-rate per 1000 of population are respectively 16·7 and 12·3. The birth-rate is 1·1 per 1000 below that of 1926, and is the lowest rate recorded since the establishment of civil registration. The death-rate is 0·7 per 1000 above that of 1926, the excess being due to the high mortality in the first and fourth quarters of the year. The infantile mortality rate (deaths under one year per 1000 births) is equal to that of 1923, the lowest on record.

As is generally known, an interest in the business of Messrs. Adam Hilger, Ltd., was acquired by Messrs. Vickers, Ltd., in 1916. On the conclusion of the War, this connexion in great part lost its utility for both parties, and an arrangement has now been made whereby the whole of the shares will be held by Mr. F. Twyman, F.R.S., and the widow and children of the late Mr. Otto Hilger. One of the latter, Mr. John Adam Hilger, now becomes a director of the firm.

Lloyd E. Jackson and George H. Johnson, senior industrial fellows of the Mellon Institute of Industrial Research, University of Pittsburgh, have been elected to honorary membership in the U.S. National Association of Dyers and Cleaners. Mr. Jackson, who is in charge of the research of the Mundatechnical Society of America, has made a number of notable contributions to garment-cleaning practice and is the joint inventor of a successful process of moth-proofing wearing apparel and house furnishings. Mr. Johnson has enjoyed much success in the investigational work he is carrying on for the Laundryowners' National Association; he is also the author of standard treatises on textiles and laundering.

Prof. E. N. da C. Andrade's recent course of Christmas Lectures at the Royal Institution on "Engines" is to be published in book form this spring by Messrs. G. Bell and Sons, Ltd.

Messrs. Bernard Quaritch, Ltd., 11 Grafton Street, W.1, have just issued another of their well-known Catalogues (No. 413). It gives the titles, and in many cases other particulars, of nearly 700 works relating to astronomy, chemistry, physics, engineering, electricity, mathematics, and navigation. The Catalogue should be seen by readers interested in these subjects.

The returns furnished for 1926 have afforded the first opportunity for a comprehensive survey of the work done by local authorities in Great Britain under the national scheme for the treatment of tuberculosis since its initiation. The Ministry of Health has therefore considered it desirable to issue a memorandum containing an analysis of these returns (Memo. 131/T.). The items are arranged under forty-six headings, and are reduced to a percentage standard for all the authorities, county councils and joint committees, county borough councils, and metropolitan borough councils. By this arrangement the different local authorities and their officers will be able to compare their own figures and results with those of others. Thus, columns 4 to 6 of the Table give some idea of the efficiency of the notification of tuberculosis in each area, which varies from 100 per cent. in some areas to so low as 70 per cent. in others. Column 7 gives the percentage of tuberculosis cases on the Dispensary Register per 100 of notifications, and the figures vary from 98 in some areas to so low as 10 in one. For England as a whole, the death-rate from all forms of tuberculosis in 1926 was 957 per million population, but in different areas it varies from a maximum of 1776 (South Shields) to a minimum of 530 (Peterborough). Of the metropolitan boroughs, Shoreditch and Bermondsey have the highest tuberculosis death-rate, and Hampstead the lowest. We notice an error in the return for Wandsworth, given as 165: it should be 865. This statistical analysis should be very valuable, and ought to be a stimulus to some of the authorities to improve their tuberculosis administration.

Applications are invited for the following appointments, on or before the dates mentioned:—An assistant lecturer in mathematics at the Bradford Technical College—The Principal, Technical College, Bradford (Feb. 11). A male senior secretary in the Academic Registrar's department, the University of London—The Principal Officer, University of London, South Kensington, S.W.7 (Applications for form by

Feb. 6, return of form by Feb. 11). A professor of public health at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, South Kensington, S.W.7 (Feb. 16). A professor of pathology at the London (Royal Free Hospital) School of Medicine for Women—The Academic Registrar, University of London, South Kensington, S.W.7 (Mar. 1). An assistant in the botany department of the University of Aberdeen—The Secretary, University, Aberdeen (Mar. 1). A science master under the Agricultural Department, Nigeria—The Secretary, Board of Education, Whitehall, S.W.1 (marked C.A.(N.)), or The Secretary, Scottish Education Department, Whitehall, S.W.1 (marked N.) (Mar. 31). A whole-time research worker, for research work on infectious diseases of the bowels, with special reference to industrial areas, at the Calcutta School of Tropical Medicine—The Director, School of Tropical Medicine and Hygiene, Calcutta (April 15). An assistant pathologist at the Royal Infirmary, Leicester — The House Governor and Secretary, Royal Infirmary, Leicester. Civilian education officers in the Royal Air Force Educational Service—The Secretary, Air Ministry, Adastral House, Kingsway, W.C.2. A temporary post in the department of mycology of the Rothamsted Experimental Station, for research work on wart disease of potatoes—The Secretary, Rothamsted Experimental Station, Harpenden, Herts. A senior unqualified assistant in the biochemical department of the Wellcome Physiological Research Laboratories, Beckenham—The Director.

ERRATUM.—Through misunderstanding of a telegraphed correction to the first footnote to the table in Mr. E. J. Williams' letter in NATURE of Jan. 28, p. 135, the expression for $(\rho-1)/(\rho+1)$ was wrongly printed $(15/8)\sigma\alpha \div (15/8)\sigma\alpha/8$ instead of $(15/8)\sigma\alpha$.

Our Astronomical Column.

PHOTOGRAPHY OF THE CORONA WITHOUT AN ECLIPSE.—G. Blunck describes in *Astr. Nachr.*, 5539, some interesting experiments on obtaining photographic images of the corona in full sunlight. He points out as the probable cause of the failure of previous attempts of this kind that they were made in too short a wave-length. He gives the percentage difference of illumination between the corona and the sky background as 0·2 per cent. at λ5000, 0·8 at λ7000, 1·7 at λ8500, 2·5 at λ9500; he states that Pinazyanol gives a maximum degree of sensitivity at λ6500, Dizyanin at λ7500, Neozyanin at λ8000. The last named makes corona photography just possible, but the author claims to have obtained a new sensitising dye called Prozyanol, which gives a maximum sensitivity at λ8500.

Full directions are given in the paper as regards the exposure, development, and subsequent treatment of the plates; there is a warning that the author himself suffered from the poisonous nature of some of the chemicals employed. Reproductions are given of three images obtained on Sept. 6 last, which strongly suggest that they are real photographs of the inner corona. An obvious test would be to take photographs by this method when the moon's disc is just outside that of the sun. If the coronal image is real, the dark outline of the moon should be traceable upon it.

M. ANTONIADI'S OBSERVATIONS OF MERCURY AND THE JOVIAN SATELLITES.—Allusion has already been made in this column to M. Antoniadi's examination of Mercury during the last three years with the great Meudon refractor, which confirmed the 88-day rotation. He gives further details of his observations in *L'Astronomie* for January, and notes that on several days observations were continued for several hours, during which no shift of the markings was discernible. He considers that there is evidence of some atmosphere on Mercury, producing thin veils of mist at times over the markings, since their darkness appeared to vary from time to time, though the conditions of our own atmosphere were appreciably the same. He gives a diagram illustrating the libration of the illuminated region arising from the eccentricity of the orbit. This was constructed by utilising the proposition that the angular motion of a planet about the empty focus is very nearly uniform.

During the same period, M. Antoniadi examined the satellites of Jupiter, of which he gave interesting drawings in *L'Astronomie* for last August. He notes the extremely high albedo of satellite II., which he states to be the highest of any body in the solar system. There had previously been no certain detection of any markings on this satellite, but a dusky marking was discerned on Sept. 14, 1926. The presence of a bright equatorial belt on satellite I., first announced by Barnard in 1893, was confirmed. Occasionally in transit across Jupiter this bright zone was alone visible, the rest of the disc being indistinguishable from the planetary background.

PARALLAXES OF BINARY STARS DEDUCED FROM ASSUMPTIONS OF THEIR MASS.—It has for a long time been the custom of the computers of the orbits of binary stars to append to their resulting elements the 'hypothetical parallax,' which is that resulting from an assumed mass of the system, generally taken either equal to that of the sun or double this. A further refinement was possible when Prof. Eddington showed that mass and absolute magnitude were correlated. Assuming the mass-luminosity relation we can make a closer approximation to the dynamical parallax than that based on the assignment of a uniform mass to all stars.

Mr. R. O. Redman applies this method to 803 stars in *Mon. Not. Roy. Ast. Soc.* for November. 120 of the stars have determined orbits; the method can be applied with greater confidence to these. The remaining stars have arcs observed which are too short for the deduction of individual orbits, but they can be used statistically, as suggested by Russell and Hertzsprung. The results for the dwarf stars are fairly consistent, and give absolute magnitudes agreeing with the Russell diagram. The mean absolute magnitudes for different spectral types are: *F*0, 2·7; *F*5, 3·4; *F*8, 3·8; *G*0, 4·1; *G*5, 4·9; *K*0, 4·7. The mean result for the solar velocity comes out 21·67 km./sec., and the mean kinetic energies for stars of the different types come out fairly uniformly, though the results for types *B*0 to *B*6, and for the giants from *F* to *K*, appear to be rather high.

On the whole, the paper adds fresh evidence in favour of the mass-luminosity relation. The individual parallaxes are printed for all the stars with determined orbits. They are especially useful for the smaller parallaxes; for the larger ones the trigonometrical values are more trustworthy.

Research Items.

Kent's Cavern.—In the *Proceedings of the Torquay Natural History Society* for 1926–27, Sir Arthur Keith describes the fragment of a human jaw which was found at a depth of 10¼ feet in the cave earth in the vestibule of Kent's Cavern. It represents part of the right half of the upper jaw, and includes the alveolar process from the middle of the socket of the canine to almost the hinder or distal margin of the socket of the second molar. Three teeth are in place—the right canine, the second right premolar, and the first right molar. The sockets for the first premolar and the second molar are empty, their teeth having fallen from the sockets after death. A small area of the lower wall of the sinus maxillaris and the basal part of the zygomatic ridge of the upper jaw are preserved, as well as a small part of the palatal process on the inner margin of the alveolar process. There is no sign of disease, but the crowns are worn flat and smooth so that a border of enamel encloses the exposed dentine. The state of the canine indicates an edge-to-edge bite. The condition of the fractured surface of the bone suggests that it was broken away before the animal matter had entirely disappeared. The bone is coloured a pinkish red, the colour of all fossil specimens from the cave earth, and there can be no doubt that it is as old as the date of the deposition of the cave earth. The teeth and jaws may very well have belonged to the same people whose remains have previously been found in the cavern, that is, the palate found in the stalagmite by Mr. Pengelly and the fragment described in the last report. It belongs to the type of modern man which includes the late palæolithic peoples of Europe.

Argentine Rock-Paintings.—Among the papers presented to the twenty-first International Congress of Americanists at the Göteborg session was a study of Argentine rock-paintings by Mr. G. A. Gardner, which has since been published with illustrations in the *Proceedings*. Although rock-paintings were known to exist in the Province of Cordoba, Mr. Gardner, in the course of investigations extending over three seasons, was able to visit and record a large number which had not previously been described. The paintings are found along the back walls of shelters eroded from the exposed edges of the horizontal strata of the triassic sandstone occurring among the mountains of Cordoba. The individual figures which compose the paintings number more than nine hundred and consist chiefly of natural objects and designs of a geometrical character. Many are incomprehensible. The commonest geometrical figures are circles, but there is a number of rectangular figures resembling gratings, while others are not unlike the European palæolithic 'tectiforms.' Combinations of dots and strokes, suggesting tallies, are found, and some figures may represent human footsteps and animal footprints. The natural objects consist largely of animals drawn in a realistic manner, of which some are the llama or the huanaco, and undoubted canines and felines. Birds are scarce but lifelike. Reptiles are represented by serpents, highly conventionalised, and a few tortoises. Recognisable vegetable forms are almost entirely absent. The absence of the human figure in most shelters was remarkable. They occurred in rudimentary and conventionalised form. A few were highly realistic, showing the dress and weapons of the Indians. Finally, representations of men on horseback appeared, clearly Spanish soldiers. Foot-soldiers are also shown. Few of the figures are in outline, most being silhouetted in colour laid on flat. Superposition is noticeable. They clearly extend over a very long time, and probably ceased with the loss of independence of the Comechingons, as these Indians were known to the Spaniards, soon after the Conquest.

Scottish Sea Trout.—As a result of the continuous work being carried out by the Scottish Fishery Board on salmon and sea trout, Mr. G. H. Nall has collected information about the sea trout from the tidal waters of the Don and Ythan (*Fisheries, Scotland, Salmon Fish.*, No. II., 1927. London: H.M. Stationery Office), both of which rivers flow out on the Aberdeenshire coast, the former with a tidal estuary one mile long, and the latter with one four miles in length. Recapture of marked fish has shown that in 1920 the sea trout present in the Don estuary were 95 per cent. finnock, and consisted for the most part of fish wandering from other rivers, only a few being natives of the Don. Interesting movements of the trout were disclosed, one having travelled in eight months a distance of 165 miles by the coast line from the Ythan to the River Teith at Callander, in which river perhaps it was originally born. In marked contrast to the mixed population in the Don waters were the fish in the Ythan estuary, nearly all of which were natives of the Ythan river. Collections in this estuary were spread over the whole of 1926, and a review of the changing composition of these trout according to age is given. The writer adds a word of warning against the danger of depleting the stock of the Don and other rivers by anglers who capture thousands of finnock from the Don estuary, many of which in the spring are ill-conditioned fish. Amongst other interesting observations is the effect of the difference in type of west coast and east coast rivers at their junction with the sea on the feeding of the sea trout, which is reflected in their scales. A new departure is made by writing this paper in non-technical language, for the advantage of anglers interested in sea-trout life.

Aeration of Aquaria.—The attention of those who desire to maintain aquaria and to provide for their aeration is directed to an account, by Prof. H. Graham Cannon and Dr. A. J. Grove, in the December issue of the *Journal of the Royal Microscopical Society*, of a simplified apparatus which has proved efficient in use. The clear description and two text-figures will enable anyone who has even a moderate amount of technical skill to make and put together the apparatus. The principle is that previously employed in the apparatus of Gemmill, namely, that water from a tap flows through a tube into the horizontal arm of a ⊣-tube and down the lower vertical arm sucking in air through the upper vertical arm. The suction tube in this apparatus, instead of being straight as in the previous types, has upon it near the top a complete twist, and "it is an advantage for this twist to be badly made" and to contain "one or two constricted bends such as the ordinary amateur glass-worker manages to produce." This apparatus should prove useful in many biological laboratories.

The Species of Ancylostoma.—B. Schwartz (*Proc. U.S. Nat. Mus*, vol. 72, Art. 1, 1927) has made an examination of specimens of *Ancylostoma pluridentatum* and confirms the validity of the species. Abnormalities in the teeth in the mouth capsule are recorded—the outermost teeth on the dorsal wall of the capsule being in some cases truncated and resembling those of *A. braziliense*, but the author considers the two species to be distinct. He gives a brief review of the species of Ancylostoma and a key by the help of which they may be differentiated. He points out that the teeth in the ventral portion of the mouth capsule are three pairs in some species (e.g. *A. caninum*); in other species (e.g. *A. duodenale*) the innermost of the three teeth is small or rudimentary; in others (e.g. *A. malayanum*) only two pairs of ventral teeth are present; and in *A. pluridentatum* and *braziliense* the inner pair is reduced in size and in some examples of the latter species is entirely absent, there being only a single pair of ventral teeth.

A PARASITE OF THE EGG OF THE LIVER FLUKE.—Prof. J. Bayley Butler and J. J. C. Buckley describe (*Sci. Proc. R. Dublin Soc.*, vol. 18, No. 45, 1927) the occurrence of a Chytridiacean parasite, *Catenaria anguillulae*, in the eggs of the liver fluke, *Fasciola hepatica*, kept in tap-water in laboratory cultures. The source of the Catenaria is believed to be the tap-water employed. The infection of the fluke egg takes place by a zoospore of Catenaria settling upon the egg-shell and piercing it obliquely, making an aperture about 0·5μ in diameter. The penetration takes place within twelve hours from the settling of the zoospore. The zoospore after entering enlarges to form a subspherical cyst from which a mycelial filament grows out into the contents of the egg and develops a series of enlargements which vary considerably in shape. The intervening unswollen parts of the mycelium become septate and form isthmuses. The enlarged parts—the sporangia—develop nutritive rhizoids which may branch. Within the sporangia, zoospores are formed and eventually escape through a dehiscence tube or beak which usually pierces the egg-shell or pushes open the operculum of the egg. No form of sexual reproduction and no resting spores have been observed. The eggs of the liver fluke will continue to live and to hatch out into miracidia if kept at laboratory temperature for a period of nine months. At any time during this period miracidia can be obtained by placing some of the eggs in test tubes in water in an incubator at 24° to 26° C. Eggs infected with Catenaria would not develop. The possibility of using Catenaria as a means of checking the infection of snails by miracidia is suggested.

ASCENT OF SAP IN TREES.—Before the recent meeting of the American Botanical Society, Dr. D. T. MacDougal, Prof. J. B. Overton, and Prof. G. M. Smith described some experiments on the passage of water up the trunks of trees (*Daily Science News Bulletin*, by Science Service, Washington). They conclude that the wood vessels in the sapwood of trees, assumed to be wholly devoted to carrying water upwards to the leaves, are to some extent air reservoirs. These air-containing vessels are, moreover, not scattered at random, but have a definite zoned arrangement which differs in different species of trees. Investigations were carried out by injecting red dye into various kinds of trees and either letting the natural suction of the leaves pull it up or pulling it up by a vacuum pump. When the suction applied was small, the dye travelled up the trunk in a natural way, and of course did not enter the vessels blocked by air. The zone of transport was thus clearly marked in red. By this means it was found that in willow the sap stream passed exclusively through wood formed late in autumn, in alder in the early spring wood only, and in walnut through the inner and outer faces of an annual ring, but not through the median portion.

SERPENTINES OF THE SHETLANDS.—Dr. F. C. Phillips makes a noteworthy contribution to the local geology of a somewhat inaccessible region, and to the general problem of the transformations undergone by ultrabasic rocks, in a paper published in the *Quar. Jour. Geol. Soc.*, pp. 622-652, 1927. The Unst intrusion, which is the largest studied, ranges from dunite and peridotite through pyroxenite to gabbro, the latter being penetrated by pegmatoid gabbro. Disseminated, banded, and massive varieties of chromite occur in the more basic serpentines, and form workable deposits. The differentiation series is thus of a normal character, and is referred to primary crystallisation *in situ*. Autometamorphism brought about serpentinisation of the ultrabasic rocks, amphibolitisation of the pyroxenes, and saussuritisation of the felspars. Dynamic action is considered to have contributed to the metamorphism at two stages: contemporary stress to the genesis of antigorite; and subsequent stress to that of various schistose products. The formation of carbonates is referred in part to the action of atmospheric weathering.

CORAL REEFS AND A MIGRATING ANTICLINE IN FIJI.—The Fiji Islands include examples of fringing, barrier, and atoll reefs in all stages of growth, and elevated barriers and atolls in various stages of dissection. The region has therefore played a considerable part in the coral-reef controversy. In the *Amer. Jour. Science* for November last, Prof. W. M. Davis uses it to show that despite many weighty opinions to the contrary, its evidence may still be unequivocally in favour of Darwin's theory. He shows that four or five roughly north-south belts of unlike reefs can be recognised, and he describes the vertical movements which the islands of each belt have suffered. It is found that the phases of movement of the western belts occur later than the corresponding phases of belts to the east. This suggests the westward propagation of a broad and shallow wave-like deformation of the ocean floor. The observed changes of level thus appear to be equivalent to the slow westward migration of a broad anticline preceded and followed by shallow synclines. The wave-length is to be measured in scores of miles, but the height from trough to crest is only a few thousand feet. This remarkable hypothesis co-ordinates in a very simple fashion a large variety of observations which hitherto have given a hopelessly confused picture of the history of this unstable region. Prof. Davis finds that the adoption of his scheme of a migrating anticline at once removes all the difficulties which Darwin's coral-reef theory has had to encounter in Fiji. He concludes, "... in spite of the many obituaries written over it in the past forty years, it may be expected to regain in the coming half-century the worldwide acceptance that it enjoyed for a generation a hundred years earlier."

OPAQUE MEAL FOR X-RAY DIAGNOSIS.—We have tested a sample of a new barium meal preparation for X-ray diagnosis prepared by the British Drug Houses, Ltd., and supplied under the name 'Shadoform.' It is put up in boxes containing the equivalent of 4 oz. chemically pure barium sulphate specially prepared, so that it forms, when mixed with cold water, a fine suspension with no tendency to settle, as the cruder forms of barium sulphate are apt to do. A little care is necessary in mixing with the water to form a suspension free from lumps, but if the instructions are followed a very good mixture results, which is palatable and of a smooth texture. The definition on the screen is good, and the meal can be manipulated easily while in the stomach. No tendency of the opaque material to settle was noticed, and excretion appeared to be satisfactory. The material is stated to be chemically pure, and hence no possibility of absorption of barium salts will arise. In this material we have a satisfactory meal which can be quickly made up.

SCATTERING OF ELECTRONS IN IONISED MEDIA.—The article by Dr. I. Langmuir in the *Zeitschrift fur Physik* of Dec. 14 on electric discharges in gases at low pressures, is a valuable review of some of the advances of recent years for which he has been directly or indirectly responsible. His methods for measuring potentials, and ionic concentrations and energies, are by now well established, and have been applied to numerous problems, but there is the curious outstanding difficulty that groups of electrons acquire a thermal distribution of velocities far more readily than can be accounted for by collisions of any ordinary type. Dr. Langmuir gives reasons for supposing that the apparent scattering cannot be an effect of either regular or aperiodic fluctuations of the discharge, as has been suggested by other authors, but the exact mechanism by which it takes place is still obscure. A large number of numerical results has, however, been collected by now, and it appears probable that the process is reversible, and that the agent responsible, whatever its nature, is in a species of thermal equilibrium with the electrons affected.

SPACE CHARGES IN ELECTROLYTES.—Various aspects of the electrical convection of liquids, many of them known to Warburg and other earlier workers, are discussed by Prof. A. Coehn and Dr. Schnurmann in the *Zeitschrift fur Physik* of Jan. 2, their object being to extend the analogy between conduction in gases and in liquids. The latter usually contain ions in such large numbers that many phenomena typical of the former are masked, but the correspondence is closer with electrolytes of one thousandth or less normality, and is especially prominent in the large fields near the surfaces of small sheathed electrodes. Here the differences in mobility of the positive and negative carriers are sufficient to set up a space charge, which can give rise to a motion of fluid *towards* the electrode. A particularly neat experiment that is described shows this effect, as well as the analogue of the electrical wind, by the reaction on a light enamelled wire, suspended in millinormal sulphuric acid with its lower end bent round, and only the extreme tip serving to give electrical connexion between the metal and fluid.

HUMIDITY TEST EQUIPMENT.—The amount of moisture in the atmosphere has a great effect on the mechanical and electrical properties of all fibrous materials. It is therefore to be expected that telephone apparatus connected to miles of insulated circuits and having closely adjusted moving parts should be specially susceptible to the effects of moisture It is necessary for telephone laboratories to have humidity test departments where the effect of various percentage humidities in the atmosphere can be accurately studied. E. B. Wood, in the *Bell Laboratories Record* for December, describes the facilities this company has in its development laboratory for making humidity tests. The equipment consists of large cork insulated rooms, small air-tight chambers, and smaller portable units. The large rooms have a capacity of about 1500 cubic feet. The temperature and humidity of each room are controlled by a system of sprays, water-cooled radiators, and electric heaters, the air from a centrifugal blower circulating through them. This apparatus enables the humidity to be kept constant at any value from 30 to 95 per cent., and the temperature at any value between 70° and 110° F. This covers the range of conditions usually existing in telephone buildings. The operation is automatic, the humidity being maintained with one per cent. accuracy and the temperature to within half a degree Fahrenheit. It is thus easy to test both raw materials and large pieces of apparatus under various operating conditions. The smaller test chambers are thoroughly heat-insulated from the outside. The humidity is controlled by the use of a solution of sulphuric acid contained in a large shallow lead tray over which the air is circulated by a fan. For temperatures below room temperatures, air cooled by contact with ice is circulated by an electric blower. For very accurate tests or for tests like corrosion tests which require a long exposure, these chambers are used. The portable units have a capacity of about eight cubic feet and are used for the inspection testing of raw materials and small manufactured articles.

REICHERT MICROSCOPES AND ACCESSORIES.—In a recently issued catalogue (List E 7), Messrs. C. Reichert of Vienna give a description of various types of their microscopes and photomicrographic apparatus for biological and mineralogical purposes. Several models of the new mono-binocular stereo-microscope are illustrated. In this instrument, the pencil of light from the objective is equally distributed between the two oculars by internal reflection from a silvered prism. The silvering is thinner on one half of the reflecting surface than on the other. This gives rise to a difference between the intensity of the rays in the left half and that in the right half of the ocular receiving the reflected portion of the light. The conditions are exactly reversed in the other ocular, which receives the light transmitted through the partially silvered surface. The parallactic differences thus produced in the pictures presented to the two eyes give rise to the stereoscopic effect. This effect is obtained without the loss of light which is involved when part of the pencil of light has to be screened off. A series of F/4 anastigmat lenses suitable for macro-photography or projection is also listed in the catalogue. These give magnifications of from 4 to 24, with focal lengths of 100 mm. to 20 mm. respectively. Amongst the various types of vertical illuminators illustrated is a polarising illuminator which can be screwed on to the microscope tube when it is desired to examine metals or ores under polarised light. The illuminator embodies a rectangular illuminating prism, a rotating polariser, illuminating lenses, filter slot, and an electric bulb as the source of light. The catalogue also includes a wide range of objectives, eyepieces, condensers, and other microscope accessories made by Messrs. Reichert, whose London agents are Messrs. Chas. Hearson and Co., Ltd., 27 Mortimer Street, W.1.

BABYLONIAN ARTIFICIAL LAPIS LAZULI.—In the *Chemiker-Zeitung* of Dec. 31, Prof. Neumann gives an interesting account of some analyses which he has recently carried out of fragments of Babylonian *artificial* lapis lazuli, dating from about 1400 B.C., from the excavations at Nippur. The high percentage of lead previously found by Bertrand has been shown to be quite erroneous, but it has been conclusively established that both cobalt and copper are present as colouring matters. It is claimed that this is the only antique glass which is definitely known to be coloured by cobalt, for in spite of frequent references in technical literature to the existence of this metal in antique glasses, they appear to have no justification. Their origin has now been traced to a faulty observation published by Davy in 1815. Although many specimens of antique glasses from the period between 1500 and 850 B.C. have been analysed by Neumann and his collaborators, cobalt has hitherto never been detected in them.

The Genetics of Cereals.

THE volume of published investigations on the genetics and cytology of cereals continues to increase, and some important problems of variation and relationships in these forms are being solved. One of the most recent of these discoveries relates to oats.

The sporadic origin of fatuoid or false wild oats from cultivated varieties has been an agricultural problem for forty years. They resemble the wild oat, *Avena fatua*, but differ in not having delayed seed-germination. An extended study of the genetics and cytology of fatuoids by Dr. C. L. Huskins (*Jour. of Genetics*, vol. 18, No. 3) has resulted in the important discovery that these are mutations resulting from chromosome irregularities in normal oats. While ordinary oats (*Avena sativa*) has forty-two chromosomes, Dr. Huskins has found that in different fatuoid strains the chromosome numbers range from forty to forty-four.

The commonest type of heterozygous fatuoid has forty-two chromosomes and segregates into normals, heterozygous and homozygous fatuoids in a 1 : 2 : 1 ratio. The segregated fatuoids frequently have a single trivalent and a univalent chromosome or, in homozygous forms, a quadrivalent. Probably such fatuoids arise through the formation of a quadrivalent chromosome in which the elements are not segregated in their proper pairs in the reduction division. Another fatuoid type has forty-one chromosomes and produces a few sterile dwarfs with forty chromosomes. The type with forty-three chromosomes produces a few sterile dwarfs with forty-four.

This work constitutes a new and striking case of correlation between chromosome content and genetic behaviour. Numerous similarities are pointed out between fatuoid oats and speltoid wheats, which also arise as variations. Both conditions apparently arise through aberrant chromosome distributions. The practical possibility is suggested that a strain of oats may be produced which does not give rise to fatuoids.

Novel results are obtained by Mr. A. E. Watkins (*Jour. of Genetics*, vol. 18, No. 3) in the study of crosses between Rivet wheat (*Triticum turgidum* with 14 pairs of chromosomes) and *T. vulgare* (vars. Yeoman and Iron) with 21 pairs. The F$_1$ is partially sterile, but was back-crossed with both parents reciprocally. Chromosome counts in these hybrids show that while the F$_1$ fertile egg-cells usually have a chromosome content intermediate between 14 and 21, the F$_1$ pollen grains with intermediate numbers are largely sterile. Thus while the eggs tend to be genetically intermediate, the 14-chromosome pollen grains are found to be carrying chiefly the *turgidum* characters, while the pollen with 17-21 chromosomes carries mainly *vulgare* characters. The keel on the glume, which distinguishes *turgidum*, can be transferred to *vulgare* by crossing. The view is expressed that there are not many factor differences between the *turgidum* chromosomes and the 14 *vulgare* chromosomes with which they pair, the *vulgare* characters being associated with the extra chromosomes. The view is therefore upheld that there is a simple polyploid relationship between the two species.

The interesting discovery is made that in some of these back-crosses the germination of the grain is largely determined by the chromosome content of the endosperm. Grains from the cross 42-chromosome ♀ × 28-chromosome ♂ are plump and germinate well, while from the reciprocal cross they are wrinkled and germinate badly. Successful germination depends on the relations between embryo and endosperm. The conclusion is reached that germination is good if all chromosomes are present in the endosperm in the diploid or triploid condition, but bad when some of them are only represented once.

In a continuation of this work (*Jour. of Genetics*, vol. 19, No. 1), Mr. Watkins has studied the inheritance of such features as waxy leaves, keeled glume, and susceptibility to *Puccinia glumarum* in F$_1$ *T. vulgare* × *T. turgidum* back-crossed with *turgidum* or *vulgare*. The results lead to the conclusion that the two species carry homologous factors in homologous paired chromosomes, while the extra *vulgare* chromosomes carry another set of very similar if not identical factors.

In crosses between the tetraploid *T. durum* and *T. vulgare*, Prof. W. P. Thompson (*Genetics*, vol. 10, p. 285) found in F$_2$ and F$_3$ some plants resembling *T. durum*, some like *T. vulgare*, and some intermediate. They have chromosome numbers corresponding to their external appearance, and the forms with intermediate numbers and appearance tend to be eliminated in F$_3$. The correlation between the *T. durum* characters and rust-resistance was broken, but since resistance evidently depends on more than one factor, it will be very difficult to get full rust-resistance in *T. vulgare* types.

Various crosses between wheat (21 chromosomes) and rye (7 chromosomes) have been made in recent years. Prof. Thompson (*Genetics*, vol. 11, p. 317) describes the cytology of a cross, using an unspecified variety of wheat as mother. This particular cross, he finds, is easily made. In the hybrid, no chromosomes pair at reduction, but the 28 separate into two groups and split lengthwise either before or after this separation. Very few F$_2$ plants were obtained, as the pollen sterility is almost complete.

Prof. G. K. Meister and his collaborators at the Saratov Experiment Station on the Volga have published a series of papers on wheat-rye hybrids, beginning in 1918, which should be more widely known. Their most recent contributions in Russian, with English or German résumés, are contained in *Jour. Exp. Agric. S.E. Eur. Russia*, vol. 4, Part I. They find that the reciprocal crosses between *vulgare* wheat (var. *erythrospermum*) and rye can be made, and they give identical results. The rye × wheat cross was made by using the local winter rye and the pollen of a winter wheat. The F$_2$ from these crosses was grown in large numbers in 1926, and many of the plants showed greatly increased fertility.

The cytology of the hybrid between *T. monococcum* ($n = 7$) and *T. turgidum* ($n = 14$) has been investigated by Prof. W. P. Thompson (*Jour. Genetics*, vol. 17, No. 1). In the pollen formation of this triploid hybrid, three to seven bivalent chromosomes appear, the remainder being unpaired. Sax, using another variety of *turgidum*, has previously reported the regular occurrence of seven bivalents. The later history of the chromosomes is also different, Thompson finding that after the bivalents separate the univalent chromosomes arrange themselves medianly and split. In the homotypic division these univalents lag, fail to divide, and wander irregularly to the poles. Sax, however, found the univalents dividing in the second division and not in the first. Thus a small difference in one of the parents appears to make a great change in the chromosome behaviour. These two varieties of *turgidum* ought to be crossed together and the hybrids studied.

Reference may be made to one more paper on wheat hybrids, by Miss Melburn and Prof. Thompson (*Amer. Jour. Bot.*, vol. 14, p. 327). In *T. spelta* ($n=21$) × *T. monococcum* ($n=7$) the hybrid is completely sterile, and the heterotypic division shows from five to no bivalent chromosomes. The remainder mostly split, but in the second division they lag and form extra nuclei. The hybrids between different types of wheat can thus be arranged in a series according to the amount of pairing of chromosomes and the irregularities in the behaviour of the univalents.

R. RUGGLES GATES.

The Introduction of Civilisation into Britain.

AT the anniversary meeting of the Royal Anthropological Institute, held on Tuesday, Jan. 24, the outgoing president, Mr. H. J. E. Peake, delivered an address on "The Introduction of Civilisation into Britain." He said that it seems certain that the art of agriculture, the first step in civilisation, was first practised in the Near East, more probably in Asia than in Africa, and that the first grain-growers were also potters. At an early date both these arts were introduced into the Ægean area and into the Plain of Hungary, and Prof. Childe has shown how they spread from the latter area to Switzerland, to the Rhine, and to the country around Liège.

Dr. Frankfort has recently pointed out the existence of a trade-route in Early Minoan times; this started from the head of the Gulf of Corinth and reached southern Italy and Sicily. Along this route passed commodities from the second city of Hissarlik. Frankfort suggests that this trade was carried farther west, and Childe has noted the presence of Early Cycladic beads in Portugal. This indicates that the elements of civilisation had reached the Atlantic coast before 2200 B.C.

Prof. Bosch-Gimpera has shown that early in the Copper Age there were two small centres of civilisation in the Iberian peninsula, one at Almeria in the south-east and the other in the south of Portugal, and that between them the Capsian natives used a rough pottery, based on leather models. These people had evidently learned the first elements of civilisation from the eastern traders, and had developed a rude civilisation that Bosch-Gimpera calls "la civilisation des grottes." He has also shown that this type of rude pottery spread so far as the Maritime Alps.

It is believed that agriculture and the potter's art reached Britain at the dawn of the Neolithic Age, and this view, as we shall see, is justified. In 1910, Mr. Reginald Smith described some round-bottomed bowls, one of which came from Mortlake, and some similar fragments from Peterborough, and pointed out that pottery of that type has been found in Finland and East Sweden. In 1925, Mr. T. D. Kendrick described two neolithic wares, one of which was found at Rodmarton and other sites in Gloucestershire and Wiltshire, the other at Mortlake and Peterborough, and in the same year Prof. O. Menghin also described these wares under the names of *Grimston-keramik* and *Peterborough-keramik*, suggesting that the former is earlier than the latter. Quite lately Mr. E. Thurlow Leeds has discussed the problem, criticising Menghin's terminology, and claiming that the first ware arrived from the south and the second from the north-east about the same time.

The best evidence comes from Windmill Hill, Avebury, now being excavated by Mr. Alexander Keiller, who has kindly allowed this information to be published. Here have been found three concentric rings of intermittent ditches, resembling those at Michelsberg, but without the distinctive tulip-shaped vase of the latter site. Pottery was found abundantly in the ditches, but in two layers separated by an almost sterile interval.

In the top layer, along with fragments of beakers, were found a number of pieces of the *Peterborough-keramik* and many sherds resembling the *Grimston-keramik*. In the lower layer, however, the prevailing ware is different, but the paste somewhat resembles that of the *Grimston-keramik*. Mrs. Keiller has restored several pots, which resemble closely some found in the lake-dwellings of Switzerland, and are called by Reinerth the *Westische-keramik*; these seem to have been introduced into Switzerland from the basins of the Rhone or Saône.

It appears likely that the elements of civilisation passed up the Rhone valley into Burgundy, where this *Westische-keramik* developed among a people who lived in fortified villages of the Michelsberg type. Thence the potter's art, and the elements of agriculture, spread into Switzerland, through the Belfort Gap into the Upper Rhine basin, where it developed into the characteristic Michelsberg type, and into the north of France and Belgium, where it spread over a large area, in which was a culture called by Bosch-Gimpera "la civilisation du silex." From this last region it reached the south of England some little time before the arrival of the *Peterborough-keramik* on the north-east coast.

Marine Oil-Engines.

IN the first Thomas Lowe Gray lecture, delivered before the Institution of Mechanical Engineers on Jan. 6, Prof. C. J. Hawkes makes an interesting survey of the past development, present status, and probable future development of the marine oil-engine. Past development is but briefly outlined. In regard to the present position, attention is directed to the fact that recent improvements in fuel consumption of marine steam turbine installations have reduced the advantage in this respect held by the oil-engine. In the tests conducted by the Marine Oil-Engine Trials Committee, the Still airless-injection two-stroke engine, consuming 6880 B.T.U., and the Doxford airless-injection opposed piston two-stroke engine, consuming 7570 B.T.U. per brake horse-power per hour, were the best performances, and it is shown that while the former has a less efficient fuel combustion, this is more than balanced by the energy recovered from the jackets and exhaust gases. It is estimated that the minimum consumptions possible at the present time are 6240 and 6820 B.T.U. per brake horse-power hour for the Still and Doxford engines respectively.

In a discussion of possible improvements it is regarded as doubtful whether the installation of waste heat boilers for the purpose of increasing the overall efficiency is justifiable. The employment of high speed engines transmitting power through hydraulic clutches and mechanical gears, which effects a saving in weight, etc., is considered to be limited to four-stroke trunk-piston engines of moderate power. The four-stroke single-acting engine has much to recommend it for moderate powers, and for larger powers, the two-stroke single acting is preferred to the four-stroke double-acting engine, the former being less complicated than, and at least as efficient as, the latter. For still larger powers the two-stroke double-acting engine is considered to be the logical line of development. Experimental engines of this latter type are being tested, and it is to be expected that a reliable two-stroke double-acting engine will be produced. There are difficulties involved in applying the oil-engine to high-powered war vessels, and a warning is expressed against applying it indiscriminately or without full consideration of its suitability for the service.

The most important stresses to which the liners, pistons, and covers are subjected are those resulting from temperature, and the real safe continuous power rating of an internal combustion engine is therefore largely dependent upon the heat flow through the liners, etc. The maximum power which can safely be developed thus depends upon the working fluid temperatures, and in order to limit the latter without reducing the mean pressure, attention must be given to the efficiency of combustion and volumetric efficiency. The efficiency of combustion is mainly dependent upon the shape of the combustion space and the movement of the air within that space. A compact combustion space is desirable, as this enables a lower compression ratio to be adopted, and the hemispherical-cavity form is considered to be the best. Whether airless or blast injection is adopted, any movement of the air in the combustion space which causes the globules of fuel to collide with each other or with the walls of the combustion space is to be avoided.

If two engines develop the same mean pressure, that with the lower volumetric efficiency must necessarily be hotter. The crank case engine is a very simple type, but it has a low volumetric efficiency and is consequently a hot and low duty engine. The four-stroke engine has a higher volumetric efficiency than the two-stroke engine because of its more effective scavenging. The introduction of port scavenging simplified the two-stroke engine at the expense of volumetric efficiency, but recent improvements have largely counteracted this. In four-stroke engines the opposed piston type is considered to have nearly as high a volumetric efficiency as the single-piston engine. Heating the induction air has an adverse effect upon volumetric efficiency. Supercharging is receiving considerable attention, but its adoption will only be justifiable if it enables higher mean pressures to be attained without increasing cycle temperatures.

Direction Finding in Navigation.

It is of great importance to aircraft to know exactly the direction in which they are travelling, and hence direction-finding equipment has been elaborated. This not only takes up much of the limited space available but is often also difficult to operate. The Air Ministry has recently developed a new method of direction finding in its design establishment at Biggin Hill. This was described on Jan. 4 to the Institution of Electrical Engineers by Messrs. T. H. Gill and N. F. S. Hecht.

The chief object of the method is to replace the direction-finding equipment on the aircraft by something very much smaller and easier to operate. A loop aerial is employed at the station, the energy radiated from the loop being a maximum in one direction and a minimum in another. The loop rotates about a vertical axis at a speed of one revolution per minute and sends out a continuous signal. This signal is interrupted when the line of minimum radiation is in the true north direction and a special Morse signal is transmitted at that moment. This enables the observer to start a chronograph. He can then find the interval between the north signal and the instant at which he is receiving minimum radiation. He thus obtains his bearing.

From the results obtained it was found that bearings could be determined with an accuracy at least equal to that obtained by any other radio method of direction finding. For the accuracy necessary for aerial navigation, this method gives a range of 200 miles.

The Air Ministry having found the 'rotating beacon' method of great use for aircraft, the Radio Research Board has made a series of experiments to find out if it would be equally useful for navigation. The results of these experiments were communicated to the Institution of Electrical Engineers by Messrs. R. L. Smith-Rose and S. R. Chapman at the same meeting.

The rotating-loop beacon was installed near Gosport and a calibration was carried out at fixed points in various directions up to a distance of 60 miles. It was found that the observed bearings were subject to a permanent deviation due to land effects. This permanent deviation was not greater than one or two degrees. At distances exceeding 60 miles, radio bearings got by this method were found to be subject to night effects similar to those obtained in radio direction finding. The errors were not serious, however, until the range exceeded 90 miles oversea. Even at great distances a fair accuracy can be obtained by taking the average value of a series of readings made in about ten or fifteen minutes. It was concluded that, up to 50 miles, the rotating beacon method gives accurate readings.

Compared with the ordinary direction-finder as used on board ship, this method has several advantages. It is independent of the steadiness of the ship, and also of the accuracy with which the ship's head is given by the compass reading at the instant of observation. No correction or compensation corresponding to the quadrantal error associated with the ship's direction-finder is necessary. It was proved, however, both theoretically and experimentally, that the limitation of the accuracy by night effects applies equally to both methods.

School Natural History.

The annual report of the Marlborough College Natural History Society, the 75th in series, shows evidence of considerable vigour under the presidency of Mr. L. G. Peirson, who is clearly a naturalist of wide attainment. The area of work is defined as ten miles from the College as centre. All the various sections (Astronomy, Archæology, Ornithology, Botany, and Entomology) seem to have vigorous boy members with to each a master having the same hobby. This year the most notable record is that of 558 species and varieties of flowering plants—evidence of close raking, though the surrounding country is singularly varied with its forest and great downs, its chalk hills and lands of high cultivation, its water meadows and valleys of rocks. It is the only place where the Icterine Warbler has been known to breed in England, and perhaps this is true of the Sand Grouse, which once seemed to bid fair to become a permanent resident of Martinsell, drinking from its dewponds.

The Society as its serious task records the meteorology of its area, the dates of flowering of plants, of appearances of all kinds of insects, and of the laying of eggs by birds, with other similar information. The splendid old records of Preston and of Smith, of Everard im Thurn, and above all of Edward Meyrick, allow comparisons of the organisms of forty to fifty years ago with those found to-day; but they are to some degree deceptive, as the area for intensive study was practically ten miles in diameter then, while it it is now twenty. For purely scientific purposes there should be subdivisions into ecological regions, and this is being attempted by similar societies elsewhere We believe, however, that boys are gregarious creatures and prefer mass rather than individual studies, and that such changes, if forced, may drive the work entirely into the hands of masters—an action which would kill the object of the Society to suggest natural history to the greatest number of boys as likely to be a delightful hobby in after life.

Clearly, with the boys as first object in view, the Society no longer publishes the research work of one of the masters—A. G. Lowndes—but this is a gain to science, not a loss, as it is readily accepted in specialist journals. He and his pupils keep and breed many animals and plants from ponds, playing with the *p*H of the water and attempting to correlate form with its variation. The technique is excellent, and Lowndes's work, in proving the negation of Labbé's results on many species of Cyclops, is important. To the boy a live animal is the thing, and we should like to see more records of the keeping and breeding of insects, worms, snails, and all invertebrates in the records of the different sections; indeed, we hold that the museum of every natural history society requires a separate gallery for such work on living animals, and we believe it would prove the popular section of its exhibits.

University and Educational Intelligence.

CAMBRIDGE.—Mr. W. B. R. King, Fellow of Magdalene College, has been awarded the Sedgwick Prize for an essay on "Contributions to the Geology of some District in which Sedgwick worked." The subject announced for the next award is "A Petrological or Stratigraphical Study of a Rock Group."

EDINBURGH.—At a meeting on Jan 23, the University Court received, with very great regret, intimation from Sir James Walker of his intention to retire from the chair of chemistry at the end of the current academical year. It was resolved to record the high appreciation of the Court of his long and distinguished service to the University.

The status of University lecturer was conferred upon Dr. Alexander Lauder, head of the Chemistry Department in the Edinburgh and East of Scotland College of Agriculture, in recognition of the responsible part which he has long taken in the teaching of chemistry in the curricula for degrees in agriculture and forestry.

The Court received with gratification intimation of a bequest by the late James Sanderson, Galashiels, of five shares of the residue of his estate, to be applied for the advancement or promotion in the University of technical and scientific study and research in the chemistry and engineering branches of the Faculty of Science. The amount of the bequest is estimated at about £35,000.

The offer was accepted of an endowment contributed by former students and others associated with the work of emeritus Prof Robert Wallace, for the foundation of a University prize, to be known as the "Wallace Prize," to be awarded to the best degree student of the third year in agriculture not holding a Vans Dunlop or Steven Scholarship.

NOTTINGHAM.—In view of the fact that the new buildings, which are being erected by Sir Jesse Boot, Bart., in the University Park, will be opened by H M. the King in July next, the authorities of University College are contemplating in the near future an appeal to increase the endowment fund of the College. Two members of the Council of the College, Mr. H. F. Lancashire, J.P., and Mr. G. Spencer, J.P., have announced their intention of endowing a chair by a joint gift of £20,000. Mr. Lancashire, who has been on the Council of the College since 1917, and was in 1926 elected a vice-president of the Court of Governors, is managing director of Messrs. J. B. Lewis and Sons, Ltd., hosiery manufacturers of Nottingham and Ilkeston. He took an active part in the reorganisation of the Textiles Department of the College in 1920, and has been for some years chairman of the Textiles Advisory Committee. It is no doubt due to his untiring energy that University College, Nottingham, now possesses possibly the finest hosiery laboratory in Great Britain. Mr. George Spencer, who was elected a member of the College Council in 1923, is head of the firm of Messrs. George Spencer and Co., hosiery manufacturers, of Nottingham, Hucknall, and Lutterworth. Mr. Spencer has for many years taken a great interest in the work of the College, and is one of the two trustees of the Revis Bequest, whereby the College acquired a sum of approximately £49,000, the interest on which is to be devoted to the provision of scholarships and studentships.

The new buildings occupy a commanding position in the new University Park, and will provide accommodation for the Faculties of Arts, Pure Science, and Economics and Commerce. The Applied Science Faculty will remain at the old building in Shakespeare Street, with the exception of the Heat Engines Laboratory connected with the Engineering Department, for which provision is being made in a special block of the new buildings. A hall of residence, accommodating eighty women students, is being erected in the University Park, and it is hoped that this will be ready for occupation during the ensuing session. The playing fields of sixteen acres are situated in the Park, within a few minutes' walk of the University and the Hostel Sir Jesse Boot bore the cost of the laying out of these, and also of the erection of the sports pavilion and the women's hostel.

OXFORD.—It is understood that during the next two terms the problems presented by the congested state of the Bodleian Library will be seriously considered by the Hebdomadal Council. The principle of separate faculty libraries has already been accepted in the case of Law and Natural Science. Novels are shelved in cellars far removed from the main library, so there are precedents for the separation of that vast mass of 'deposited' literature, much of it of doubtful value, that at present dilutes, and renders difficult of access, the more valuable portions of the library.

A lecture delivered on Jan. 26 on "Isocrates in England" in ancient Greek by the Public Orator is in the nature of a revival of a lecture founded in 1583, the year in which Galileo watched the pendulum in the Duomo at Florence. It was noticeable that the lecturer does not include natural science among the subjects to be taught to boys between 16 and 18 years of age; evidently pendulums are still swinging.

Dr. F. A. Dixey, late Sub-Warden, Wills Medical Fellow and Bursar of Wadham College, has been elected to an emeritus fellowship.

Calendar of Customs and Festivals.

February 5.

ST. AGATHA, martyred at Catania under Decius by the governor Quintianus. She was miraculously healed of the wounds inflicted on her by torture, by the apostle Peter, who appeared to her carrying a vase and accompanied by an angel. After her death, an unknown young man accompanied by a hundred children placed an inscribed marble tablet on her tomb and then disappeared and was never seen again.

February 10.

ST. SCHOLASTICA, a festival formerly observed at Oxford, when the burgesses attended at St. Mary's. The origin of the custom is said to have been a quarrel between the citizens and students of the University which took place on this date in the year 1354. The outbreak lasted for some days, several students being killed; and all the religious crosses of the city were destroyed. For this offence the King, who was then at Woodstock, deprived the city of many privileges, bestowing them on the University, and the Bishop of London forbade the administration of the sacraments to the citizens, a sentence which was not removed until 1357, when a total abrogation was granted on the condition that St. Scholastica's day should be celebrated by a number of masses for the souls of the students, the mayor and bailiffs, with 60 burgesses, being bound under penalty of 100 marks to swear at St. Mary's Church observance of the customary rights of the University. Further, each of the burgesses was to offer individually on the altar one penny to be divided between the poor and the Curate of St. Mary.

SEASONAL FESTIVALS.—In popular tradition and custom there is a tendency to confuse the celebration of St. Bridget's Day with Candlemas. Candlemas observances, such as the kindling of the Yule Log and the dismantling of the decorative foliage, characteristic of winter or the Christmas season, mark the change from one season to another and the passing of winter. St. Bridget celebrates the opening of spring. Both traditions rest on a division of the year by seasons rather than months, and therefore belong to an earlier phase of calendrical arrangement.

It must be remembered that Feb. 1, the date of the feast of St. Bridget, falls twelve days later in the Old Style year than in the revised calendar and is by that much a more appropriate date for the celebration of the coming of spring. The effect of intercalation is seen in popular custom in the belief that, during the early part of the year, especially between Christmas and Twelfth Night, each day of a certain period foretells the weather in the coming year. The Celtic calendar, to reconcile the lunar and solar years, intercalated a thirty days' month in two and a half years, and other members of the Indo-European group followed the same system. In Brittany the last six days of the old year and the first six of the new were known as 'supplementary days.' Each was called by the name of a month, and each prognosticated the weather of the month in the coming year with which it corresponded. It is also a Brahmanic belief that the twelve intercalated days are an 'image' of the coming year.

In the Highlands of Scotland, the survival of the older method of reckoning is seen in the popular system of fixing periods of time by reference to seasons and often in such a way as to cut across the monthly divisions. The Celtic calendar divided the year into four seasons, but there is evidence of an older division into two seasons; one beginning on May 1 at Beltane and the other on Nov. 1 at Samhain, the latter marking the beginning of the Celtic year. Earrach, spring, began on Feb. 1; Foghainhan, the festival of Lughnasadh, the harvest feast, took place on Aug. 1. This festival would appear to be the last to be added to make the fourfold division of the year. That festivals were observed on May 1, Aug. 1, and Nov. 1—the two latter preserved in Lammas and All Souls respectively—is well known, but for the occurrence of a spring festival the evidence rests principally upon what may be deduced from the surviving tradition in the observance of St. Bridget's Day.

The form and divisions of a calendar, together with the ritual observances attached to it, are governed by the occupations of the people or group with whom it originated. The fourfold division of the year derives from the natural divisions into which the changing seasons group the activities of an agricultural community. On the other hand, the year of a pastoral community naturally falls into two divisions, one beginning when the flocks and herds are sent out to graze at the coming of the warm season, and the other when they are brought home at the setting in of cold weather. If, therefore, the Celtic year is correctly interpreted as showing a change from the twofold to the fourfold division, it would point to a corresponding change in occupation from pastoral to agricultural, the ceremonial fires of Beltane on May 1 still being lit for the purification of the flocks and herds before they were sent out to graze.

The twofold division of the year was apparently characteristic of the Aryan-speaking peoples. It appears in the Slavic calendar and also in the Norwegian. The latter is of a very primitive type. It was divided into summer and winter only; the former opened on April 14, and the latter on Nov. 14. There were two great festivals, one in early summer and the second at the beginning of winter, when there is reason to believe the year began.

The association of Candlemas in ecclesiastical tradition with a Roman festival points to a connexion between Christian observance and Roman custom, of which it is not an isolated instance. The impulse towards purification on entering upon a new phase of existence which can be observed in the practices of the New Year, and is of wide distribution, appears in both the Christian and the Roman calendar. Until the reform of Julius Cæsar, the Roman year began in March. The feasts of the Roman calendar in its early form can be traced back to the observances and customs of a primitive agricultural community. As might be expected from a people at that stage of culture, the last month of the old year was a time of solemn purification and of renewal of the spiritual influences which protected the individual and society as a whole. The name of the month of February is said to be derived from Februus, an instrument of purification. The chief feasts of the month were directed to this end. The Terminalia, Feb. 23, renewed the solemn ritual of the placing of the boundary stones. The Parentalia, which lasted over nine days, renewed the bonds between the family and their dead, culminating in a celebration by the whole State on Feb. 21: while the Lupercalia, in a ceremony of which much is obscure, by a solemn procession around the Palatine on Feb. 15, the participants in which were girt with skins, apparently purified the sacred area from evil influences of the past and reinforced its sacred character for the coming year. It is scarcely necessary to dwell upon the resemblance between this period of solemn observance and the Christian Lent.

Societies and Academies.

London.

Royal Society, Jan. 26.—**G. I. Taylor**: The deformation of crystals of β-brass. β-brass, which has a crystal structure similar to that of α-iron, behaves in a similar, though not identical, manner when distorted. The peculiar feature of the distortion of iron crystals, namely, the fact that slip does not occur on a definite crystallographic plane, is repeated in β-brass within a certain range of orientations of the crystal axes in the specimen. On the other hand, in another range of orientations, slip occurs on a definite crystal plane of type {110}. The variation in resistance to shear which occurs as the plane of slip rotates about the direction of slip determines which type occurs. This variation is calculated from the experimental results within the range to which they apply, and it is shown that resistance to shear is least when the plane of slip coincides with a crystal plane of type {110}. On either side of this position shear stress increases linearly.

F. Horton, A. C. Davies, and U. Andrewes: Critical potentials for soft X-ray excitation. An account of an extension of work on the critical potentials for the excitation of soft X-rays from the elements chromium, manganese, iron, cobalt, nickel, copper, and zinc, using steady deflexion methods instead of the ordinary timing method of measuring with the electrometer the photoelectric currents produced by the rays. This greatly facilitated the taking of series of observations, and in consequence additional critical points have been detected. It is suggested that some critical potentials may be characteristic of the arrangement of atoms at the surface of the target, as distinct from others which would be characteristic of encounters between electrons and isolated atoms. At low voltages, the efficiency of soft X-ray excitation is nearly the same for all the elements investigated.

H. Gough: The behaviour of a single crystal of α-iron subjected to alternating torsional stresses. Subjected to alternating torsional stresses, the direction of slip coincides with that of the most highly stressed principal line of atoms, and four such possible directions of slip exist within the crystal, each being parallel to the normal to one of the four set of octahedral planes, and at any point on the circumference of the crystal there exists a plane on which the value of the shear stress on the plane resolved in one of the octahedral directions is a maximum. Slip only occurs on one of the following two combinations of planes: (*a*) 110 and 123, or (*b*) 112 and 123; it cannot occur on a 112 plane combined with a 110 plane.

R. W. James, I. Waller, and D. R. Hartree: An investigation into the existence of zero-point energy in the rock-salt lattice by an X-ray diffraction method. Within certain limits of frequency the *F* curve, or atomic scattering curve, of an atom for X-radiation can be calculated by applying the classical law of scattering to the distribution of charge represented by the Schrodinger density-distribution for the atom. The *F* curves calculated from the Schrodinger distributions for the ions Na^+ and Cl^-, obtained theoretically by an approximate method, and those obtained experimentally from observations on the rock-salt crystal at different temperatures, agree very closely, assuming that the crystal possesses zero-point energy of amount half a quantum per degree of freedom, as proposed by Planck.

H. T. Flint and J. W. Fisher: The fundamental equation of wave mechanics and the metrics of space. The wave equation introduced into quantum mechanics by Schrodinger is deduced from a law of metrics in space-time. This law is expressed by a simple divergence equation, which, by making use of Eddington's extension of Weyl's theory, may be converted exactly into the real part of the wave equation. It appears that quantum phenomena are directly related to the gauge factor, λ, of space-time which occupies the place of ψ in Schrodinger's theory.

B. Swirles: The internal conversion of γ-rays. The internal conversion of γ-rays is discussed on the lines of the quantum mechanics. The problem is that of the perturbation of a hydrogen atom of nuclear charge *Z* by a Hertzian doublet at its centre. An expression is obtained for the coefficient of absorption in the *K*-levels, which gives values about one-eighth smaller than the experimental ones; the discrepancy is probably due to a neglect of the screening by the other electrons.

A. Muller: On the input limit of an X-ray tube with a circular focus. The well-known heating in the focus of an X-ray tube puts certain limits to the input. An attempt is here made to calculate the limiting input, assuming that the focus spot is a circle.

L. F. Bates: The specific heats of ferromagnetic substances. The thermal and magnetic behaviour of a simple ferromagnetic compound of manganese and arsenic has been studied. This compound has a critical point at 45° C. Heat is very rapidly absorbed when the substance changes from the ferromagnetic to the paramagnetic state. The thermal and magnetic phenomena are intimately connected, and with magnetic change there is associated a heat of transformation. Magnetic phenomena in the region of the critical point are evidence of transformation, which in this case appears to be complete at that temperature, but, in general, may reach only a particular stage at the critical point.

W. Jevons: The ultra-violet band-system of carbon monosulphide and its relation to those of carbon monoxide (the '4th positive' bands) and silicon monoxide. Martin (1913) discovered a band-system in the region λ2837—λ2436 in the carbon disulphide tube discharge and in the sulphur-fed carbon arc. On experimental evidence he ascribed it to CS. More extensive measurements have been made of the heads in Martin's spectrograms and vibrational quantum numbers n', n'' assigned. The two heads of each double-headed band belong to the *R* and *Q* branches respectively The bands are probably of the simplest type, with single *R*, *Q*, and *P* branches. The CS, and also the SiO, systems are attributed to the electronic transition $1^1P \rightarrow 1^1S$, where 1^1S is the normal state and 1^1P the second excited state of the molecule. The CO and SiO systems are more nearly alike than the CO and CS systems as regards (*a*) the ratio of system-origin to comparable atomic line, (*b*) the proportional increase in vibrational frequency, and (*c*) the intensity distribution, and, therefore, the proportional decrease in moment of inertia.

P. E. Shaw and C. S. Jex: Tribo-electricity and friction. (Part 2.) Prepared glass rods are rubbed by various solid elements in an apparatus designed to give constant conditions of pressure and surface. Some elements never, with any type of glass surface tried, show negative charge. These are carbon, cadmium, iron, lead, bismuth, silver, copper, gold, platinum, magnesium, tungsten. Other elements show ultimate negative charge. These are zinc, tin, aluminium, antimony, nickel, cobalt, selenium, telurium, arsenic, chromium, tantalum, and sulphur. Residual acid, alkali, or water films on the glass have a predominating influence on the charging. Rubbing *in vacuo* yields results similar to those found in the open air, at least in the typical cases tried. (Part 3.)

Commercial textile material is unsuitable for precise tribo-electric experiments, on account of natural and artificial impurities. Well-cleansed material acts consistently on the various solid elements. The arrangement of the various elements according to their charges on textiles and glass corresponds closely to their chemical qualities. Anomalies are found in the case of some strongly electro-positive elements, which appear in two places in the tribo-electric series.

G. P. Thomson: Experiments on the diffraction of cathode rays. The patterns formed by cathode rays scattered by thin films of aluminium, gold, celluloid, and an unknown substance are closely similar to those obtained with X-rays in the 'power method.' The sizes of the patterns agree to 5 per cent. with those predicted on the de Broglie theory of wave mechanics, regarding the phenomenon as one of diffraction of the phase waves associated with the electrons.

B. F. J. Schonland: (1) The polarity of thunderstorms. A discussion is given of the tests available for determining the polarity of thunderclouds and further observations at Somerset East are described, which appear to support the conclusions of Craib and the writer that the polarity of these storms was positive. (2) The interchange of electricity between thunderclouds and the earth. Observations were made to examine the part played by (*a*) point-discharge currents, (*b*) lightning discharges between cloud and ground, and (*c*) charged rain, in the electrical interchange between an active thundercloud and the earth. From these observations, (*a*) and (*b*) are estimated to produce continuous currents of the order of 2·1 and 0·1 (equivalent) amperes respectively, in an upward direction, and (*c*) to produce a reverse downward current of the order of 0·02 amp. The resultant current is thus estimated at 2·2 amp. in such a direction as to convey a negative charge to earth.

H. Gregory and **S. Marshall**: The thermal conductivities of oxygen and nitrogen. The apparatus used was the vertical compensated hot-wire type employed in the determination of the thermal conductivity of carbon dioxide. The results are 589×10^{-7} cal. cm.$^{-1}$ sec.$^{-1}$ deg.$^{-1}$ for oxygen, and 580×10^{-7} cal. cm.$^{-1}$ sec.$^{-1}$ deg.$^{-1}$ for nitrogen, at 0° C. and are consistent with those of Gregory and Archer for the thermal conductivity of air at 0° C.

E. V. Appleton and **J. A. Ratcliffe**: On a method of determining the state of polarity of downcoming wireless waves. For downcoming waves of 400 metres wave-length in England, the polarisation is approximately circular with a right-handed sense of rotation. According to the magneto-ionic theory of atmospheric deflexion of wireless waves, in which the influence of the earth's magnetic field is taken into account, such right-handed elliptical polarisation might be expected if the effective electrical carriers are of electronic mass.

H. Glauert: The effect of compressibility on the lift of an aerofoil. The effect of compressibility of air on the characteristics of an aerofoil moving with velocity approaching that of sound is of fundamental importance for design of high-speed airscrews. A solution has been obtained of the general equations for the motion of a non-viscous compressible fluid at a large distance from a point-vortex, in a stream of uniform velocity, and an approximate expression has been derived for the effect of compressibility on lift of aerofoil. The analysis appears valid up to a velocity of order 0·6 velocity of sound. In this range, slope of curve of lift coefficient against angle of incidence increases without any change in angle of no-lift.

W. A. Bone, D. M. Newitt, and **C. M. Smith**: Gaseous combustion at high pressures (Part 9). The effects have been studied of increasing pressure between 1 and 125 atmos. upon the 'explosion limits' of hydrogen–air, methane–air, and carbonic oxide–air mixtures respectively. In the first two, the 'lower' limit remains practically unchanged, but the range of explosibility widens with increasing pressure, particularly for methane-air mixtures. On the other hand, the 'limits of explosibility' of carbon monoxide-air mixtures materially diminish with increasing pressure. The same holds true when nitrogen from air is replaced by argon or helium, but more so when argon is the diluent.

A. T. Doodson: The analysis of tidal observations. The advantages claimed for the new method described are (1) systematic condensation of the observational material; tidal constituents not treated independently of one another until the last stage of analysis; (2) results readily show whether analysis is complete or not; (3) perturbations of one constituent upon another are adequately eliminated; (4) correlation with astronomical arguments is very much simplified.

H. R. Lang: On the measurement of the specific heat of aniline with temperature, using the continuous-flow electric method. Two types of flow calorimeter were used. It was extremely difficult to get the liquid perfectly dry, as it was hygroscopic. The very small water-content was determined in each case from the freezing-point. A separate investigation gave the relation between water-content and freezing-point, a small correction being applied to give the value for perfectly dry aniline. Between 5° and 75° C., rate of change of specific heat with temperature increases with rising temperature.

T. H. Havelock: Wave resistance. Direct proofs are given of certain expressions used in previous calculations. The method can readily be extended to more general cases. The results obtained can be applied to give the wave resistance for any distribution of doublets in any positions and directions in a uniform stream.

K. Yardley: An X-ray study of some simple derivatives of ethane (Part 1). The substances C_2Cl_6, C_2Br_6, $C_2Cl_4Br_2$ (two forms), C_2Br_5F, $C_2Cl_3Br_3$, $C_2Br_4(CH_3)_2$ (two forms), form an isomorphous series, crystallising in the space-group Q_h^{16}. The unit-cell contains four plano-symmetrical molecules. Two halogen atoms and the two carbon atoms lie in the symmetry plane (010). The formula of both forms of $C_2Cl_4Br_2$ appears to be $CCl_3 . CClBr_2$. The two CH_3 groups in $C_2Br_4(CH_3)_2$ lie in the symmetry plane. (Part 2.) Attempts to obtain X-ray data for $C_2(CH_3)_6$ and $C_2(CH_3)_5Br$ failed because of the extreme speed with which these substances volatilised. $C_2Br_4(CH_3)_2$ possesses a third (tetragonal) form, which bears no apparent resemblance to the two forms described in Part 1. $C_2(CH_3)_4Br_2$ forms needle-like tetragonal crystals, the molecules themselves simulating tetragonal symmetry. They occupy approximately face-centred positions in a unit-cell of dimensions $10{\cdot}45^2 \times 8{\cdot}14A^3$. The orthorhombic cell of $C_2(CH_3)_5OH$ may be divided into two pseudo-tetragonal parts; in each the arrangement of molecules resembles that in the unit-cell of $C_2(CH_3)_4Br_2$. The space-group is C_{2v}^{11}.

Physical Society, Dec. 9.—**H. P. Walmsley**: The scattering of light by individual particles in smokes. Applying the expression given by Maxwell for the number of collisions that occur between two sets of spherical uncharged molecules in a gas to the case of a smoke the particles of which cover a wide range of sizes, it appears that particles of a given set collide less frequently with themselves than with those in sets of much larger or much smaller size. If the particles unite on contact, one would expect therefore that the units of the resulting aggregates would differ greatly in size. This result is at variance with the deductions of Patterson and Whytlaw Gray from experimental data.—**J. J. Manley**: On the construction and standardisation of an interferometer pressure gauge. A Michelson interferometer is applied to the determination of gas pressures ranging from 0·0001 to 20 mm. of mercury. The gauge can be set instantaneously and the pressure which obtained at the moment of setting measured at leisure.—**Anne I. Anderson**: The dielectric constant of liquid bromine. An account is given of a re-determination of the dielectric constant of liquid bromine, the value found being 3·119 at 15° C., and at a frequency of 187,000 per sec., with a temperature coefficient of $-0·00191$ referred to 0° C. Applying the dipole theory of Debye and Gans to the results, a value of $0·40 \times 10^{-18}$ is deduced for the electric moment of the bromine molecule Br_2.

PARIS.

Academy of Sciences, Dec. 27.—**Charles Moureu** and **Charles Dufraisse**: Autoxidation and antioxygen action. The theory of antioxygen action. The theory of antioxygen action, proposed by the authors in previous communications, appears to be opposed to certain consequences of the general theories of catalysis, since, in fact, a certain displacement of equilibrium under the action of a catalyst is implied. The difficulty comes down to the definition of a catalyst, which is critically discussed.—**Pierre Termier**: The Vanoise-Mont Pourri tectonic, in the Savoy Alps, is not separable from the Briançonnais stratum.—**V. Grignard** and **G. Mingasson**: The mechanism of the catalytic hydrogenation of the phenols. Use is made of the catalytic addition of hydrogen under reduced pressure (with nickel catalyst) to bring out the intermediate phases of the hydrogenation of phenols. The experimental results prove that the addition of hydrogen to phenols follows the course that could be predicted from the Kékulé formula: the two double bonds not adjacent to the hydroxyl group taking up hydrogen giving the enol form of the corresponding cyclohexanone.—**C. Camichel, P. Dupin**, and **M. Teissié-Solier**: The application of the law of similitude to the periods of formation of the alternate vortices of Bénard-Karman.—**B. Berloty**: Observations of the passage of Mercury across the sun, November 10, 1927, made at the Observatory of Ksara.—**R. Maire** and **L. Emberger**: General sketch of our phytogeographical knowledge of Morocco: the climatic stages of vegetation.—**Maurice Gevrey**: Conditions at the limits relating to tangential differentials.—**Jules Drach**: Determination of the linear elements of Liouville for which the equation of the geodesic lines admits at least two rational integrals of the first differential.—**Léon Pomey**: Non-linear differential and integral equations.—**Floran Vasilesco**: The problem of Dirichlet.—**W. Gontcharoff**: The determination of functions by the zeros of their differentials.—**Četajev**: The equations of Poincaré.—**Émile Merlin**: The distribution of velocities and densities in a heterogeneous fluid in rotation.—**W. Margoulis**: The application of nomography to the study of turbo-machines with screws.—**Maurice Girault**: The geometrical construction of the profiles of wings by conformal representation of a circle.—**Th. Vautier**: The increase of the intensity and of the duration of extinction of sound.—**Thadée Peczalski**: The dispersion of metals in solid salts under the action of the electric current.—**F. Bedeau** and **J. de Mare**: Continuous hissing produced by a piezoelectric quartz, emitting simultaneously two high frequency oscillations.—**Ernest Esclangon**: The optical dissymetry of space and the laws of reflection.—**Auguste Le Thomas**: The 'heredity' of castings. The quality of castings from a particular foundry appears to be connected with the foundry and to be independent of the chemical composition. The explanation of this 'structural heredity' is not known.—**Leon Guillet**: Remarks on the preceding communication.—**A. Mailhe** and **Renaudie**: The transformation of alcohols into petrol. The vapours of normal butyl alcohol passed over uranous oxide heated to 420° C.–440° C. gave a gas containing a high proportion of ethylenic hydrocarbons and a liquid containing butyric aldehyde and a mixture of hydrocarbons boiling between 80° C. and 125° C.—**Paul Combes**: The stratigraphic chronometer of Saint-Nazaire-Penhoët and the age of Glozel. The section exposed by Kerviler in the Penhoët basin in 1877 would place the Neolithic nearer the Christian age than has hitherto been supposed, about seven centuries B.C.—**Joseph Devaux**: The formation of glaciers by the daily fusion and nocturnal regelation of néves. J. Vallot has shown that at the top of Mt. Blanc the snow is transformed progressively into ice, although the temperature remains always below $-15°$ C. The older view of fusion and regelation, however, is not incorrect, and can be shown to be taking place in certain cases.—**H. Colin** and **Ch. Neyron de Méons**: The inulin of the asphodel.—**Pierre Lesâge**: The influence of heat on the potential energy of plants.—**George F. Jaubert**: The destruction of *Galleria mellonella* by means of chloropicrin. The efficacy of chloropicrin in destroying this pest in beehives is proved.—**Gabriel Bertrand**: Remarks on the preceding communication.—**H. Lassalle**: The evaluation of the neuro-muscular excitability. Theoretical discussion.—**Charles Kayser** and **Albert Ginglinger**: The systematic variations and signification of the respiratory quotient as a function of the temperature in animals.—**H. Simonnet** and **G. Tanret**: The hypoglycæmic properties of galegine sulphate.—**Jean Saidman**: The biological properties of X-rays of 8 Angström units. X-rays of wavelength 8 A. are absorbed by the superficial layers of the epidermis and do not reach the vascular zone, alterations in which produce dermatitis. The roots of the hair are also unattacked. These rays have been successfully applied to the treatment of chronic eczema of the hands.—**Marcel Duval**: The molecular concentration of the blood of the snail. The influence of the state of activity of the animal. Starting with the known fact that the activity of the snail is markedly affected by the presence or absence of moisture in the air, experiments were devised to see how far the humidity factor regulated the activity by a physico-chemical process. The molecular concentration of the blood was measured during the hibernating state and in summer when moving and when inert within the shell. The expected relation between the activity of *Helix pomata* and the molecular concentration of its blood was proved experimentally.—**Y. Manouélian** and **J. Viala**: Nerve cells and the virulence of the salivary glands.—**Georges Blanc** and **J. Caminopetros**: Experimental researches on the antidysentery vaccination in man.—**Burnet**: The impossibility of vaccinating the goat against *M. melitensis* with large doses of vaccine.

Diary of Societies.

SATURDAY, FEBRUARY 4.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—H. C. Colles: Musical London from the Restoration to Handel (1660–1759) (I.).

ASSOCIATION OF WOMEN SCIENCE TEACHERS (Annual General Meeting) (at St. Paul's Girls' School), at 4.30.—Sir John Russell: The Growth of Crops: Applications of Botany and Chemistry to Country Life (Lecture).

RURAL CONSTRUCTION ASSOCIATION (at London School of Economics), at 5.30.—R. Borlase Matthews: Electricity in Rural Life.

WESTERN JUNIOR GAS ASSOCIATION.—Thomas Hardie: Address.—Dr. E. W. Smith: Modern Tendencies in Carbonising Practice.

MONDAY, FEBRUARY 6.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Prof. F. O. Bower: Obituary Notice of A. Anstruther Lawson.—Prof. W. H. Lang: The Flora of the Old Red Sandstone of Scotland: a General Survey.—E. B. Bailey: Schist Geology: Braemar, Glen Cluny, and Glen Shee.—Dr. H. H. Read: Highland Schists of Middle Deeside.—*To be read by title only:*—Prof. D. M. Y. Sommerville: An Analysis of Preferential Voting.—Sir Thomas Muir: The Theory of Jacobians from 1885 to 1919.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—Rev. A. H. Finn: The Miraculous in Holy Scripture.

BIOCHEMICAL SOCIETY (at Lister Institute), at 5.—H. Jephcott and A. L. Bacharach: The Quantitative Estimation of Vitamin D.—A. L. Bacharach and E. Allchorne: The Vitamin B Content of Malt Extract.—M. G. White and J. J. Willaman: The Alcoholic Fermentation of Pentoses by Fusarium Lini.—Prof. A. V. Hill: Increased Anaerobic Metabolism in Muscle following Stimulation.—D. Jordan Lloyd and W. B. Pleass: The Effect of Nitrates on the Absorption of Water by Gelatin.—H. W. Kinnersley, R. A. Peters, and V. Reader: Metabolic Constancy in the Pigeon.—R. T. Brain and H. D. Kay: Phosphate Excretion.—R. P. Cook and B. Woolf: The Deamination and Synthesis of l-aspartic Acid by Bacteria.—R. Robison and K. M. Soames: Calcification in Vitro.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Percy Sargent: The Surgery of the Posterior Cranial Fossa.

SOCIETY OF ENGINEERS (at Geological Society), at 6.—C. H. J. Clayton: The National Rivers and their Functions (Presidential Address).—D. C. Fidler: Presentation of Premiums awarded in 1927.

INSTITUTION OF AUTOMOBILE ENGINEERS (Western Centre) (at Merchant Venturers' Technical College, Bristol), at 6.45.—W. West: Foundry Work.—C. T. Skipper: Machining Operations on a Six-Cylinder Block.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—F. Selley and others: Discussion on Domestic Water Heating.

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—F. H. Carr: Some Problems Encountered in Making Fine Chemicals.

SURVEYORS' INSTITUTION (at Institution of Civil Engineers), at 8.—sL. Crouch: The Landlord and Tenant Act, 1927.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—T. A. Barns: In Portuguese West Africa.

TUESDAY, FEBRUARY 7.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. A. P. Newton: The Settlement of the Dominions, 1758–1870.

Zoological Society of London, at 5.30.—Secretary: Report on the Additions to the Society's Menagerie during the months of October, November, December 1927, and January 1928.—D. Seth Smith: Exhibition of a Blue Variety of the Masked Love-bird (*Agapornis personata*).—Dr. P. R. Lowe: Studies and Observations bearing on the Phylogeny of the Ostrich and its Allies.—S. Zuckerman: The Age-changes in the Chimpanzee, with Special Reference to Growth of Brain, Eruption of Teeth, and Estimate of Age, with a Note on the Taungs Ape.—F. F. Laidlaw and the late H. Campion: Notes on Oriental Dragonflies (Odonata) with Descriptions of New Species.

Institution of Civil Engineers, at 6.

London Natural History Society (at Winchester House, E.C.), at 6.30.—Annual Spring Exhibition.—Miss C. H. Longfield: By Rail, Road, and River, through the Heart of South America.—Rev. H. J. Gamble: My Week-end in the Home of Tutankhamen (Lectures).

Institution of Electrical Engineers (East-Midland Sub-Centre) (at Loughborough College), at 6.45.—C. D. Gibb: Modern Reaction Turbines.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—F. H. Clough: Stability of Large Power Systems.

Institute of Metals (Birmingham Local Section) (jointly with Birmingham Metallurgical Society and Staffordshire Iron and Steel Institute) (at Engineers' Club, Birmingham), at 7.—Prof. F. C. Lea: Testing of Metals.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.—A. Keighley: North Palestine and Syria.

Institute of Metals (North-East Coast Local Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Dr. J. A. Smythe and C. H. Pearson: Demonstration of Mechanical Testing of Metals.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.

Royal Aeronautical Society (jointly with Institution of Automobile Engineers) (at Royal Society of Arts), at 7.45.—Wing Comdr. J. G. V. Fowler: The Repair and Maintenance of Aero Engines.

WEDNESDAY, February 8.

Royal College of Surgeons of England, at 5.—Prof. G. Grey Turner: The Treatment of Congenital Defects of the Bladder and Urethra by Implantation of the Ureters into the Bowel, with a Record of 14 Personal Cases.

Geological Society of London, at 5.30.—Prof. W. J. Pugh: The Geology of the District around Dinas Mawddwy (Merioneth).

Royal Society of Medicine (Sub-Section of Proctology), at 5.30.—F. J. McCann: An Operation for Prolapse of the Rectum in the Female.—Z. Cope: The Treatment of Irreducible Sigmoido-rectal Intussusception in Old People.—W. B. Gabriel: Four Cases of Small Gut Obstruction Round Colostomies.—Demonstration by Dr. P. H. Manson-Bahr: Sigmoidoscopic Appearances in Colitis.

British Psychological Society (Industrial Section) (at Royal Anthropological Institute), at 6.—Dr. M. Culpin and others: Discussion on Occupational Neuroses.

Institute of Metals (Swansea Local Section) (at Thomas' Café, Swansea), at 7.—N. Alan: Gases in Metals, with Special Reference to Copper.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Graduate Section) (Middlesbrough), at 7.30.—E. Graham: Some Notes on Ship Construction.

Royal Society of Arts, at 8.—H. D. Wilkinson: Theatre Lighting.

THURSDAY, February 9.

Royal Society, at 4.30.—Prof. O. W. Richardson: On the Extraction of Electrons from Cold Conductors in Intense Electric Fields.—R. H. Fowler: (a) The Restored Electron Theory of Metals and Thermionic Formulæ; (b) The Photo-electric Threshold Frequency and the Thermionic Work Function.—P. A. M. Dirac: The Quantum Theory of the Electron.—Dr. H. T. Flint and Prof. O. W. Richardson: On a Minimum Proper Time and its Application to (1) the Number of the Chemical Elements, (2) Some Uncertain Relations.—*To be read in title only*:—Dr. H. Jeffreys: Some Cases of Instability of Fluids.—Dr. H. T. Flint: Relativity and the Quantum Theory.—C. A. Clemmow: A Theory of Internal Ballistics based on a Pressure Index Law of Burning for Propellants.—Prof. H. A. Wilson: The Emission of Light by Flames containing Sodium and the Absorption of Light by Mercury Vapour.—C. N. Hinshelwood and H. W. Thompson: The Kinetics of the Combination of Hydrogen and Oxygen.—E. T. Copson: On Electrostatics in a Gravitational Field.—K. Darwin: Examples of the Zeeman Effect at Intermediate Strengths of Magnetic Field.—W. R. Brode: The Analysis of the Absorption Spectrum of Cobalt Chloride in concentrated Hydrochloric Acid.

Royal Institution of Great Britain, at 5.15.—Sir William Bragg: From Faraday's Note Books (2). "Crispations": The Forms of Fluids on Vibrating Surfaces.

Royal Photographic Society of Great Britain (Informal Meeting of Colour Group), at 7.—T. J. Offer: Instantaneous Colour Photography in the Theatre.

Society of Dyers and Colourists (Midlands Section) (at Nottingham University College), at 7.30.—A. J. Hall: Action of Alkalies on Cotton and Art Silk.

Institution of Electrical Engineers (Dundee Sub-Centre) (at University College, Dundee), at 7.30.—J. Conway: Development of the Rotary Converter.

Institute of Metals (London Local Section) (at 83 Pall Mall), at 7.30.—R. G. Batson: Properties of Metals and Alloys at High Temperatures.

Optical Society (at Imperial College of Science and Technology) (Annual General Meeting), at 7.30.

Royal Society of Medicine (Ophthalmology and Neurology Sections), at 8.30.—Dr. J. Collier (Neurology), F. A. Williamson-Noble (Ophthalmology), Dr. A. Feiling, Dr. J. R. Perdrau, M. L. Hine, R. Foster Moore, and Dr. W. J. Adie: Special Discussion on Ocular Complications of Encephalitis Lethargica.

Oil and Colour Chemists' Association.

FRIDAY, February 10.

Royal Society of Arts (Indian Meeting), at 4.30.—Sir Edward A. Gait: Bihar and Orissa (Sir George Birdwood Memorial Lecture).

Royal Astronomical Society (Anniversary Meeting), at 5.—Presidential Address; Presentation of the Gold Medal to Prof. R. A. Sampson, and of the Jackson-Gwilt Medal to Dr. Steavenson.

Medical Officers of Schools Association (Annual General Meeting) (at 11 Chandos Street, W.), at 5.—Dr. A. A. Mumford: The School Medical Officer of the Future.

Physical Society (at Imperial College of Science and Technology), at 5.—Dr. A. Ferguson and E. J. Irons: A Simple Graphical Method for the Determination of Galvanometer and Fluxmeter Constants, with a Note on the Measurement of Intense Magnetic Fields.—Dr. C. J. Smith: On a Method of Constructing the Caustic Curve formed by Refraction at Plane Surfaces.—J. C. Hudson: The Application of Electrical Resistance Measurements to the Study of Atmospheric Corrosion of Metals.

Royal College of Surgeons of England, at 5.—Prof. J. H. Sheldon: An Undescribed Disease of Bone.

Malacological Society of London (at Linnean Society), at 6.

North-East Coast Institution of Engineers and Shipbuilders (Newcastle-upon-Tyne), at 6.—J. E. Southcombe: Some Contributions to the Theory and Practice of Lubrication.

Institution of Electrical Engineers (North-Western Centre) (jointly with Manchester Association of Engineers) (at Engineers' Club, Manchester), at 7.15.—E. J. Parish: Inspection Methods.

Junior Institution of Engineers, at 7.30.—Prof. H. P. Philpot: Some Principles of Investigation in Engineering Work.

Institute of Metals (Sheffield Local Section) (in Applied Science Department, Sheffield University), at 7.30.—J. B. Forster: Casting.

Society of Chemical Industry (Chemical Engineering Group) (jointly with Society of Dyers and Colourists) (at Chemical Society), at 8.—E. A. Alliott: Dry Cleaning and Finishing Machinery.

Royal Institution of Great Britain, at 9.—Prof. B. Melvill Jones: Research on the Control of Aeroplanes.

Society of Dyers and Colourists (Scottish Section) (at Glasgow).—Dr. H. H. Hodgson: The Relation between Laboratory and Bulk Production.

SATURDAY, February 11.

Royal Institution of Great Britain, at 3.—H. C. Colles: Musical London from the Restoration to Handel (1660–1759) (2).

PUBLIC LECTURES.

SATURDAY, February 4.

Horniman Museum (Forest Hill), at 3.30.—Mrs. R. Aitken: Village Life in High Castile.

MONDAY, February 6.

London School of Economics and Political Science, at 5.—Dr. H. P. Biggar: The Discovery of Canada from Cabot to Champlain.

Gresham College, at 6.—G. P. Bailey: Modern Science and Daily Life: Rare Gases of the Atmosphere.

East Anglian Institute of Agriculture (Chelmsford), at 7.—W. R. Day: The Cultivation of the Cricket Bat Willow.

TUESDAY, February 7.

King's College, at 5.30.—Prof. S. Alexander: Emergence, or Primary, Secondary and Tertiary Qualities of Things. (Succeeding Lectures on Feb. 14 and 21.)

University College, at 5.15.—Miss E. Jeffries Davis: More London Place-Names. (Succeeding Lectures on Feb. 14, 21, 28, and Mar. 6.)

WEDNESDAY, February 8.

Royal Institute of Public Health, at 4.30.—Dr. W. Norwood East: Some Problems of Forensic Psychiatry.

University College, at 5.30.—I. C. Grondahl: Norwegian Country Life, Customs and Sayings. (Succeeding Lectures on Feb. 15 and 22.)

THURSDAY, February 9.

University College, at 5.30.—Prof. P. Fleming: Relics of Monastic London.

FRIDAY, February 10.

Guy's Hospital Medical School, at 5.30.—G. Simpson: The Surgery of the Kidney and Ureter. (Succeeding Lectures on Feb. 17 and 24.)

University College, at 5.30.—E. J. Holmyard: Chemistry in Mediæval Islam.

SATURDAY, February 11.

Horniman Museum (Forest Hill), at 3.30.—M. A. Phillips: In the Haunts of the Sea-birds.

CONFERENCE.

Tuesday, February 7.

Conference on Power for Cultivation and Haulage on the Farm (at Rothamsted Experimental Station), at 11.30 a.m.—Chairman: Sir Merrik Burrell.

H. C. Burford: The Design of a General Purpose Tractor.
G. W. Watson: The Care of the Tractor on the Farm.
H. Porter: Practical Experience of Power on the Farm.
R. D. Mozer: Rotary Cultivation.
Dr. B. A. Keen: Horse and Mechanical Power in Farm Operations.

SATURDAY, FEBRUARY 11, 1928.

The Great Barrier Reef.

ELSEWHERE in this issue an account is given of the expedition shortly to visit the Great Barrier Reef, one of the chief natural wonders of the world, a breakwater built by still-living organisms along a continental coast for 1300 miles. Starting from Harvey Bay, 120 miles north of Brisbane, the reef extends from lat. 25° S. to join up to New Guinea in 9° S. Much broken in its southern two degrees, where is the great Capricorn Passage, by which ships enter, the barrier soon becomes more marked, until in places it forms an almost continuous breakwater, the edge becoming again less defined as the influence of the water of the Fly River is felt. Its distance from the mainland varies from more than 100 miles in the north and south to an average of not more than 30 miles over a long stretch in the middle, though in places outstanding capes reduce the enclosed channel (lagoon) to less than ten miles in breadth. Cairns, the chief town near the proposed headquarters of the expedition, is situated at the south end of this area about lat. 16° 30′ S. Near it are broad channels through the great seaward reef, and a fairly clear lagoon, though with reefs exposed at low tide. About half-way to the outer barrier lies a small reef with an islet, upon which the members of the expedition will camp, absolutely in the centre of their work.

The Barrier Reef was first explored by Capt. Cook, and it was a little north of Cairns where he ran on to a reef, afterwards careening his ship for repair in Endeavour River, now the site of Cooktown. His course thence was inside the reef for about 70 miles, but navigation for sail was difficult within the narrowing lagoon, and he passed out to seaward, afterwards re-entering through Providential Channel, 150 miles north, and exploring Torres Straits. The coast bristles with his names, among which may be cited Capes Upstart, Flattery, Capricorn, and Tribulation, Repulse and Trinity Bays, Possession Island and Thirsty Sound. Other explorers were King, Flinders, and Bligh, but the first systematic survey was by H.M.S. *Fly* and *Bramble* in 1842–6 under Capt. Blackwood, with J. Beete Jukes as naturalist to the survey. This was merely carrying on the generous hospitality of the Admiralty to scientific men, so profitable in the association of Banks with Cook, and continuous from then for 160 years to the present day. This survey followed on that of the Maldive Islands by Capt. Moresby in the previous decade, and laid the foundation of the accurate knowledge of the topography of great reef areas.

Both surveys were remarkable achievements with the instruments and means at that time at the disposal of the surveyors, and that of the *Fly* materially assisted in the opening up of Queensland. Some of the barrier was shown to consist of linearly extending reefs, while in other places it was represented by a series of ring- or atoll-shaped structures. The passages through this reef have clearly no close correlation with the drainage of the land, for the north of Queensland drains rather to the west than to the east. The enclosed lagoon has nowhere a greater depth than 50 fm., and in few places more than 30 fm. It was found to be studded with many shoals, most of which reach the surface and there spread out, submerged ridges and patches being comparatively scarce. Outside, in the Coral Sea, were discovered a whole series of reefs, some with cays, all within the 1000 fm. line and extending towards New Caledonia. To the north is a deep of about 2500 fm., lying south of the eastern horn of New Guinea, just north of which is the tiny Planet Deep (4998 fm.), surrounded on three sides by land. Lastly, it was shown that an elevation of less than 10 fm. would join Australia to New Guinea, and that shallow water extended far west, the north of Australia having indeed one of the largest areas of shallow sea in the world.

The views of Darwin on the formation of coral reefs were published in 1837, and his wonderful book on the subject in 1842. The suggestion of subsidence as the predisposing cause in the formation of reefs met with almost universal acceptance, and for the Barrier Reef was endorsed by Savile Kent, who presented a book of delightful photographs rather than of scientific consideration. Indeed, he only sought spots for his hobby, and we have to fall back upon Jukes for accurate and studied observations. Murray doubted whether Darwin's views had the general applicability demanded, and Alexander Agassiz differed *in toto* after visiting the Barrier Reef in 1896 in very bad weather. The first boring at Funafuti was then being undertaken, and a subsequent boring showed a vertical thickness of 200 fm. of limestone material. Other workers proved that this could not have been directly formed by upgrowth at a greater depth than 50 fm., for 'reef-building' corals were shown to depend for their nutrition on commensal algæ, and all plant growth stops below this same depth owing to an absence of sufficient light. At the same time, heavy, stony algæ (Lithothamnioneæ) were seen to be the main reef builders in shallow water under heavy seas, with other herbaceous calcareous forms to provide small material to fill up any hollows. It was stated that the lagoon topography was not consistent with subsidence and that lagoons are being added to by solution of limestone. To this was added the removal of fine material in suspension to form vast areas of coral mud covering some millions of square miles of the ocean floor in coral regions.

Research was mainly directed on the subsidence side to the study of the embayments of islands, and Prof. Davis has pointed out the extraordinary resemblance between the coasts within the Great Barrier Reef with its numerous capes and outlying islets to those of Fiji, Tahiti, and other groups, which he claims proves his contentions. On the whole, the geological study of elevated reefs in Fiji, West Indies, and other lands is said to help on the same side; but anomalies exist, and there is often difficulty in settling the geological periods of the limestones. Meantime the history of Falcon Island, Tonga, has given striking proof of the possibility of the views of Wharton that many of the isolated atolls and submerged atoll banks of the world have foundations produced by submarine eruptions, the products of which are loose material, easily cut down to 40 or 50 fm. by the waves.

A discovery of volcanic ash off Providence Reef, between Madagascar and Seychelles, gives confirmation of this view, and indeed is the first definite indication of the foundations of any existing reef. Next came the gradual appreciation of the fact that most coral islands largely owe their existence to a change of level of at least 10 feet in the sea, a change usually explained by polar glaciation. Finally, Daly suggested that by the same means an alteration of as much as 250 ft. was possible, and that land, cut down to sea-level by oceanic agencies, might, by the melting of the polar ice caps, be submerged to this depth and so provide foundations for extensive post-Pleistocene reefs. This view would seem peculiarly attractive as applying to the Great Barrier Reef area, but Prof. Davis points out that the broadness of the continental slope off Queensland as compared with its narrowness in the southern half of the same coast is not consistent with the view, and that there are also material differences in the two coast lines.

Thus the controversy went on until the Governor of Queensland (the Right Hon. Sir Matthew Nathan), Prof. Richards, and others, formed the Great Barrier Reef Committee of Australia, recognising that the problem could only be solved by repeated observations on a coral reef area, preferably connected with a great land mass, the geological conditions of which could be studied for hundreds of miles inland. The Great Barrier Reef lies near the centre of the disturbance of earth movements, which, according to one theory, produced arcs of reefs and islands on the crests of earth waves flowing over the Pacific. It also fringes part of a continent where the newer problems of weight pressures (isostasy) are being considered. The committee studied the geology of coastal areas, examined reefs and islands, and finally put down a boring on a reef near Cairns in the lagoon channel. It met with very great difficulties, owing to the loosely coherent nature of the material in the bore, but reached 100 fm. The bottom part contained many foraminifera and other organisms, which occur under quite shallow water conditions and on reef flats, so that, if the living forms are confined to such depths and are in their place of growth in the bore, there has been a subsidence of 600 ft.

In 1913 the late Dr. A. G. Mayor had made an ecological survey of Murray Island at the north end of the Great Barrier, mapping out the zones of life and correlating the distribution of species of corals with physical conditions. These he continued from 1915 until 1920 in Samoa, testing his conclusions experimentally by transplantation and other experiments. The biological work of the Australian committee had cognisance of this, but all the plans for further development were held up by the death of Mr. Charles Hedley, the biological director, and also, no doubt, by the universal scarcity of competent marine biologists. In these circumstances the committee invited the formation of a British committee to send out a biological expedition for the study of the many problems that arose as to the feeding, the rate of growth, the seasonal reproduction, the distribution, etc., of corals, foraminifera, sponges, and marine algæ, and as to the interrelations of these forms to one another in the building of reefs.

A study of the organisms together should lead to conclusions as to whether surface reefs are growing out, either seawards or lagoonwards. Linear surface changes can be perhaps better ascertained by aerial photography with three fixed permanent marks on some small reefs, these being repeated each decade; but unfortunately the changes are often subsurface, and sounding and dredging have to be undertaken as well. These should also give an account of upgrowth and loss on the lagoon floor, and for the former the association of the organic complex with temperature, with salinity, with acidity of the sea (pH) and with currents acting as food carriers, is all-important. Half-a-dozen genera of foraminifera, forming part of the cementing sand, live in the floating plankton of the outer ocean and pass within the reefs to destruction. Many of the building animals feed on small animal and plant organisms of the same habitat, and the plant builders depend on nitrates, largely produced there, as well as upon sunlight. The nutrition of the organic life is ultimately a matter of the chemical constituents and of the physical conditions of the water, and the governance of the varied seasons of reproduction is almost certainly the same, phenomena never up to the present studied in tropical seas. The expedition is to camp in its little area and to make weekly observations on such matters for twelve consecutive months. In its plan is revealed the advance of science, research directing its aims to the basal conditions governing all organic life, the period of general explorations being largely passed.

Finally, the Great Barrier Reef, with its 100,000 square miles of area capable of being developed for economic ends, may well be a matter of importance to the Empire in the future, and the close study of coral growth should at once yield results of value to navigators in all coral seas. Fish become of value in proportion to their quality, to their quantity, and especially to the distance of the fishing grounds from dense areas of consumption As yet they may be of little importance, but the advance of freezing processes has brought to the fore the catching and distribution of fish from all seas. There is also the sea slug (trepang), an elongated starfish, dried and exported to China for soup. Good eating oysters are to be found in places, as well as many other edible molluscs. Next comes the pearl shell, used for buttons, for inlay, and for all sorts of beautiful ends, its value increased almost half by its contained pearls. There is a world shortage now in this, and the supply can no longer be left to Nature, since its possibilities of cultivation are proved; and Torres Straits is the home of its most valuable species. The uncontested sovereignty of the British Empire over the Great Barrier Reef from shore to ocean, however broad, suggests peculiar potentialities for such farming. Depths, too, are suitable for sponges, which likewise have to be grown by man, and there are other shells and products that can be sold. For all these—and indeed for fisheries of all classes—the first knowledge required is that of the water and its contained food, for these are fundamental to the knowledge of the optimum conditions of growth, of reproduction, and of distribution, on which commercial success depends.

We need say no more except to commend most highly this new development in research, the co-operation in equal partnership towards the highest scientific aims of committees thoroughly representative of Great Britain and Australia. We feel that this is as things should be, and we trust that no questions of finance or of personnel will hinder the successful prosecution of this expedition. The sunshine of the tropics brings into prominence biological processes, such as the metabolism of lime, which in our northern climate are weakly developed and intermittent. The great Pacific Ocean forms a vast reservoir of water which ensures a constancy never to be found in the North Sea and the fluctuating English Channel. The co-ordinated work of zoologist, botanist, physiologist, chemist, and geographer for twelve consecutive months on the Barrier Reef should furnish results giving a new point of departure for our knowledge of the conditions of all life.

Science and Theology.

(1) *The Way of Modernism: and other Essays.* By the Rev. J. F. Bethune-Baker. Pp. vi + 150. (Cambridge: At the University Press, 1927.) 6*s*. net.

Coulter, Ellsworth Faris, Charles H. Judd, John M. Dodson, Charles B. Davenport, E. Davenport, C.-E. A. Winslow, Horatio Hackett Newman. Pp. xi + 427 + 5 plates. (New York and London: D. Appleton and Co., 1927.) 12*s*. 6*d*. net.

(1) THE theological readjustments which seem called for in consequence of an acceptance of evolution have recently been prominently discussed. Thus the time is opportune for the appearance of Prof. Bethune-Baker's essays. The writer's qualification is that he is an expert in the history of the development of Christian theology, who thus knows exactly what meaning orthodox dogmas originally had for those who formulated them. The importance of the theory of evolution for Christian theology cannot be exaggerated, since it supplies entirely new views both about man and about creation.

"I need not remind you that in our doctrine of Christ we are stating a doctrine both of God and of Man. We interpret Christ according to the ideas we have of God and Man, and our ideas to-day of God and Man are very different from those of Christians of the fifth century" (p. 13).

Man is no longer to be regarded as the victim of a 'fall,' but as the result of a long and painful struggle upwards. Thus, if the traditional anthropology is wrong, the traditional scheme of redemption requires revision. With regard to the traditional doctrine of creation, it depended on a view of God which regarded Him as apart from the world, whereas we tend to conceive of Him as immanent both in the world and in man. The traditional doctrine of the incarnation was framed to fit in both with the idea of fallen man who was apart from and distinct from God, and of a God who was, so to speak, outside His creation. It had to explain how two such incompatible natures could ever come to be combined.

"We do not get much help from our tradional statements of doctrine. Our technical definitions are frankly dualistic. They treat God and Man as two distinct real existences ('substances'), each with its own special characteristics, which are incapable of being blended or fused into one" (p. 100).

Prof. Bethune-Baker holds that the new evolutionary theology must present Christ as the consummator, that is, as one in whom the divine design for man finds expression. This design, which in Christ emerged in fullness, "is at the heart of the universe, the secret of its process, and its goal." This idea is found in the Fourth Gospel, with its doctrine of the divine 'logos,' or purpose, which was visibly embodied, so that "the ideal was seen, full of grace and truth, in all its attractiveness and power of revealing their true selves to men." It is found also, in language of astonishing modernity, in the famous eighth chapter of *Romans*, and elsewhere in the writings of St. Paul. This means that, although in Christ we have "an emergence of a new consciousness and a new quality, a new type, as it were, of manhood," yet the divine purpose which emerged in Him is one with the purpose that has emerged in Nature and in man. That is to say, there is no gulf between man and God; they are not incompatible substances. This is the sort of Christian theology, essentially orthodox as it is, which students of science can understand; and Prof. Bethune-Baker deserves their gratitude.

(2) Canon Raven's book contains his Hulsean and Noble Lectures. As a distinguished naturalist as well as theologian, he speaks with authority for students of natural science. As Prof. Bethune-Baker's book is a protest against the antithesis between God and man, so Canon Raven's is a protest against a dualism of God and Nature. The manifestation of God in His creation has been neglected.

> "There has been a general tendency in Christian thought to regard nature and the natural order, if not as inherently evil, at least as spiritually meaningless, a mere stage on which the divine drama of regeneration was to be played, or even a hostile environment from which men were to be set free" (p. 6).

Yet the modern outlook does not appear to make things easier:

> "To earlier generations it was easier to assume that as God had made the world, it must all be very good, save where His plan had been upset by the wiles of Satan. . . . Of the awful indifference and machine-like fixity and terrifying scale of things, as of the evidences of struggle and cruelty and waste and suffering in the animal world, there was little consciousness. The outlook was frankly anthropocentric" (p. 9).

Canon Raven cannot reconcile modern cosmic pessimism with Christian theology. The God who is revealed in Nature must also be the God revealed in Christ (that is, in theological terms, "the Father" and "the Son" must be "of one substance"). This can only be grasped by thinking in terms of creative process. Its lower products may seem incongruous with its higher, but the process is one, and its purpose one. In other words, the unity of the world lies in the law of its development, and what that law is may be seen in the highest product of the process. Here Canon Raven brings us to the same point as Prof. Bethune-Baker, *i.e.* to the Johannine christology. The Word, or Purpose, was in Christ; in Him "the Word became flesh." Canon Raven interprets the evolutionary process, following Profs. Lloyd Morgan and Alexander, in terms of 'emergence,' and quotes the former as saying that "Emergent evolution is from first to last a revelation and manifestation of divine purpose" (p. 85).

What will specially appeal in this book to working biologists is the well-documented criticism of Weismannism in Chap. ii.; but the whole work may be said to be the ablest attempt made in recent years systematically to interpret the results of biological science in terms congruous to Christian belief.

(3) Sir Francis Younghusband's speculations about the possibility of life on the stars and of its nature, will interest many. Very few astronomers, perhaps, will have spent night after night, as has Sir Francis, in the waste and silent places of the earth under the vast vault of heaven, beholding "the terrors and splendours of the night." After all, if one star in a million were attended by such another planet as our own, "there would be at least five thousand suitable abodes." The poetic imagination of Dante led him to believe in the existence of such beings as Sir Francis suggests to us: beings far higher than ourselves, who may somehow shed abroad influences to reach as far as ourselves. This book, though speculative, is one of very great charm; it provides a pleasant antidote to the austere mathematical abstractions to which modern astronomy must confine itself.

(4) Dr. Shailer Mathews has edited a valuable collection of essays by experts in the different branches of natural science. The first part of the book gives us the facts, and the second part tells how this knowledge can be used for the benefit of humanity. The third and final section, written by Dr. Shailer Mathews himself, shows how science justifies the religious life and gives content to religious thought. Altogether a most valuable book, which ought not to be without its effect on the Fundamentalist controversy in America.

J. C. HARDWICK.

Coal Carbonisation.

(1) *Coal Carbonization, High and Low Temperature: a Treatise on the Principles and Processes of Manufacturing Coke and Semi-Coke.* By John Roberts. (The Specialists' Series.) Pp. xvi + 406. (London: Sir Isaac Pitman and Sons, Ltd., 1927.) 25*s*. net.

(2) *Oil and Retortable Materials: a Handbook on the Utilisation of Coal, Torbanite, Cannel and Oil Shale.* By George W. Halse. Pp. vii + 146. (London: C. Griffin and Co., Ltd., 1927.) 7*s*. 6*d*. net.

THESE two books exemplify the activity which is now being displayed in following up the possibilities of the carbonisation process in various directions, and the results of operating by methods removed in varying degrees from the standards of normal coke-oven and gas-works practice, including the treatment of raw materials other than ordinary coal.

In the first and longer work, the stress is laid upon carbonisation as a means of producing different varieties of solid fuel which can be grouped under the name of coke, while Mr. Halse's smaller book is inspired by the purpose of discussing what may be done to increase the production of liquid fuel in Great Britain by the utilisation of such materials as torbanite, cannel, and oil shale.

(1) Mr. Roberts's book sets out to deal with coal carbonisation at high and low temperatures, and there are several features in it which are noticeable and give it a character of its own. In the first place, more than in any other book with which the reviewer is acquainted, special attention is directed to the nature of the changes which coal undergoes in its transformation into coke, and the different factors which operate in determining the character of the final solid product of carbonisation. It is only during the last decade that our want of knowledge under this head has been properly appreciated, so that much of the experimental work which Mr. Roberts calls upon in his account of the coking process is quite recent, and has not come into book form before. He has marshalled his facts and arguments well, and reproduces a number of useful illustrations of coke formation under various conditions.

It would, however, be a mistake to suggest that this study of coke formation is the only outstanding characteristic of the author's treatment of his subject. Equally remarkable is the amount of ground which has been covered in gathering material of another kind bearing upon the numerous plants and processes which have been described in technical literature, and in patent specifications, for the carbonisation of coal at low and high temperatures. The book is packed with information of this kind, and it is given, so far as the reviewer has been able to see, with accuracy and clearness, collecting a mass of descriptive detail into a comparatively small volume of 400 pages.

This mode of treatment, to which we have become accustomed in books on technical subjects, although not always followed out with the same care and knowledge as is forthcoming from the author, has, however, its accompanying disadvantage. So many processes are described that the author plainly cannot claim first-hand knowledge of all, and is compelled to retail the claims made with little comment. The critical examination of processes necessary for their real evaluation is out of the question, from space considerations alone. The quantitative thermal and chemical aspects are necessarily given very little attention, partly from this want of space, and partly because the requisite data have never been acquired or never published.

Such a work as this should be read, however, by the serious student with the limitation above outlined clearly in mind, and that being taken for granted, he will find both interest and profit in following up the many ramifications of technical practice brought to his notice.

The newer developments are naturally in the main those associated with processes of low temperature carbonisation, and that for a very good reason. The success of such processes, if and when attained, depends largely upon their power of speeding up the transformation of carbonisation (as compared with the standard high temperature processes), so lowering installation and working costs per unit of coal carbonised. The fact that lower temperatures of working are employed permits the use of steel instead of fire-clay as the principal material of construction in the plant, and consequently permits also the use of new mechanica devices. This principle is employed in many of the plants of which descriptions are given by the author.

One feature of the book which is interesting although it does not seem to find a natural place under the title, is a complete account of the author's views on the origin of anthracite, according to which the assumption has to be made that bituminous coal has been converted into anthracite by attaining a temperature of from 500° to 550° in the earth's crust while subject to great pressure It should not be understood by the reader that the actual development of so high a temperature has been so far demonstrated as to be generally accepted.

Summarising, one may say that Mr. Roberts's book may be welcomed as treating the process of carbonisation comprehensively and well from a viewpoint which is not that of the gas engineer or the coke-oven manager, but has its advantages in making for originality and breadth. It is wel printed, and the illustrations are numerous and well chosen for the author's purpose.

(2) Mr. Halse's book is much smaller and, as stated above, its range is much more limited. No attempt is made to describe processes in detail or to discuss the chemistry of them in any critica spirit. Its chief point of usefulness is in bringing together information, which until now has been scattered, on torbanites, cannels, and oil shales, in explaining what are the characteristics of these materials, and what processes have so far been

employed in utilising them for the supply of liquid fuel.• The work of a number of authorities has been drawn upon in order to bring out the distinctions between coals, lignites, torbanites, etc., and this information has been usefully tabulated.

At the end of the book is a two-page glossary, but some of the information contained therein, such as that gels are " stable colloidal aggregations," does not in itself carry the average reader very far, while surely the definition of a British Thermal Unit and of a calorie might be taken for granted. The author claims quite rightly in justifying his book that " the importance of liquid fuel to national life cannot be over-estimated, and a right understanding of what has been accomplished towards making additional supplies available is of great moment." J. W. C.

Magnetism and the Electromagnetic Field.

Handbuch der Physik. Herausgegeben von H. Geiger und Karl Scheel. Band 15: *Magnetismus; Elektromagnetisches Feld.* Redigiert von W. Westphal. Pp. vii + 532. (Berlin: Julius Springer, 1927.) 43·50 gold marks.

IN a comprehensive treatise in many volumes there is a great danger of lack of co-ordination between the parts. Few individuals, and unfortunately not all scientific libraries, however, are likely to purchase all the twenty-four volumes of the " Handbuch der Physik," and in practice the utility of the work will depend largely on the independent value of single volumes. These suffer considerably from the general tendency to avoid any overlapping in the ' Handbuch ' as a whole. Co-ordination is partly obtained by the systematic subdivision of the subject matter—in this respect the ' Handbuch ' has been carefully planned—but the value both of the work as a whole and of the single volumes would have been greatly enhanced by a much more lavish use of cross-references. The lack of an author index is a considerable drawback. There are numerous footnote references, but short selected bibliographies to the separate sections, which would have been a useful feature, are only given in a few cases.

The ' Handbuch ' may perhaps best be regarded as an ordered series of short monographs. Those in the present volume fall into two groups, dealing with magnetism and the electromagnetic field. In the first chapter, on magnetostatics, P. Hertz, using the conception of magnetic charge, develops in great detail the mathematical theory which may be built up on a few simple fundamental laws. The action at a distance and medium viewpoints are adopted successively and shown to lead to equivalent results. The treatment proceeds in stages of increasing generality—from the case where the permeability is unity to that where there is hysteresis—in a way which conduces to clearness but not to brevity. The second chapter, also by Hertz, is on the magnetic fields due to currents.

W. Steinhaus gives an account of the magnetic properties of materials in Chap. iii. The section on dia- and para-magnetism, which occupies 15 pages out of the total of 270 on magnetism in this volume, is very inadequate as an account of the present state of knowledge. The description of ferromagnetic phenomena, however, in particular of hysteresis and of temperature and magneto-mechanical effects, is excellent. It is unfortunate that the important investigations of the last few years on single crystals of iron could not receive notice. The specific heat of ferromagnetics, and the magneto-caloric effect, might have been briefly discussed in connexion with the molecular field hypothesis.

A most interesting chapter on ferromagnetic substances is contributed by E. Gumlich. The extensive material is admirably summarised. The effect of thermal and mechanical treatment, and of impurities, on the magnetic properties of iron and steel is fully described. A short section follows on cobalt and nickel, and ' cryptoferromagnetic ' manganese. Finally, alloys of ferromagnetic metals and Heusler alloys are dealt with.

G. Angenheister gives an account of the observations on terrestrial magnetism and their interpretation in Chap. v. (The measuring instruments and methods, as for magnetism generally, are described in another volume.) The observational results are presented with the aid of a number of recent world and regional magnetic charts. The formal analysis of the results is given, and the various theories of the earth's permanent magnetism—none of them satisfactory—are considered. The character of the periodic changes is described, and then that of the aperiodic, and the two theories which connect these with the emission of electrically-charged particles, and of radiation from the sun, are discussed.

The second part of the volume opens with a chapter by S. Valentiner on the fundamental phenomena of electromagnetic induction, essentially those described by Faraday, presented clearly in the light of later developments. Coefficients of induction are worked out for a number of special cases, and a most useful list of references is given.

R. Schmidt deals clearly and very completely with the analytical and graphical methods for the treatment of alternating currents in Chap. ii. In the third chapter, on electric oscillations, E. Alberti considers the behaviour of single and coupled closed circuits, the effect of iron cores, and also oscillations in open circuits.

The last chapter, on the dispersion and absorption of electric waves, is by W. Romanoff. An outline of the theories and of the experimental methods is first given. It is only in the last few years that convenient valve methods for the production of short undamped waves have become available, which will enable satisfactory experiments to be carried out in this difficult region of investigation. Much of the older work is of doubtful value, but the coherent account of some of the more satisfactory results, and their comparison with theory, will form a valuable basis for further research.

Although the volume suffers from the drawbacks which have been mentioned, it is a mine of information on those particular aspects of physics with which it deals. As an example of book production the standard is high. The printing of both the text and diagrams is admirable.

E. C. S.

Our Bookshelf.

The Druids: a Study in Keltic Prehistory. By T. D. Kendrick. Pp. xiv + 227. (London: Methuen and Co., Ltd., 1927.) 12*s.* 6*d.* net.

IN this book Mr. Kendrick is decidedly an iconoclast. Ideas relating to the Druids which have taken a firm hold on the popular imagination are carefully weighed and found wanting. First among them is the tradition which connects the Druids with Stonehenge and other megalithic monuments. Mr. Kendrick shows that this connexion cannot be traced back to a period earlier than the seventeenth century, when Aubrey claimed Stonehenge for the Druids and interest in these functionaries was beginning to revive after their eclipse dating from the Saxon invasion. It is to be noted that Geoffrey of Monmouth in his well-known description of Stonehenge makes no allusion to the Druids.

Mr. Kendrick's aim is to clear away the cloud of misunderstanding and vain imagining which has gathered round the Druids by bringing together in a critical synthesis all that is known positively from historical records of their organisation, ritual, and beliefs, together with such inferences as may legitimately be drawn from the archæological data relating to the period. A recital and examination of the multitudinous theories which have been formulated on the subject is therefore beyond his purpose, and his own speculations on the subject have been reduced to a minimum. It is to be noted that although he rejects the responsibility of the Druids for Stonehenge and megalithic monuments, necessarily as the monuments must for the most part belong to an earlier period, he suggests that they may possibly have used them at some later period for their ritual observances. Gratitude is due to Mr. Kendrick for his admirably judicious and judicial sifting of the material, even if he has dispelled some cherished illusions in the cold light of reason.

Gmelins Handbuch der anorganischen Chemie. Achte völlig neu bearbeitete Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. Bearbeitet von R. J. Meyer. *System-Nummer* 2: *Wasserstoff.* Pp. xvi + v + 273. (Berlin und Leipzig: Verlag Chemie G.m.b.H., 1927.) n.p.

MORE than half this volume is devoted to a detailed description of the physical properties of hydrogen, which is perhaps not astonishing when one considers the exceptional interest which belongs to the simplest of the elements. In the discussion of atomic structure the term hydrogen-nucleus (*H-Kern*) is generally used, but Rutherford's convenient term 'proton' is mentioned as being preferable to other suggested names. Atomic weight estimations are given in detail from the time of Berzelius to the year 1926.

Mechanical, thermal, optical, magnetic, and electrical properties of hydrogen and also hydrogen-electrodes are discussed fully. Considerable space is also devoted to the technical preparation of hydrogen on a large scale. The chemical section deals with the behaviour of the gas towards metallic compounds and aqueous solutions of salts, with catalytic hydrogenation and with analytical methods. There is also a special account of the hydrides, which are classified as (*a*) *metallic* hydrides, in which varying amounts of the gas can be absorbed into a homogeneous phase, the character of the metal itself and its lattice structure remaining intact; (*b*) *salt-like* hydrides, which are definitely polar, in which the hydrogen possesses the character of a negative ion (*e.g.* hydrides of the alkali and alkaline earth metals); and (*c*) *gaseous* hydrides, which are either gases or volatile liquids at ordinary temperatures. This class includes hydrides of bismuth and lead. The volume closes with an account of triatomic hydrogen, H_3 produced with the aid of positive rays.

Theoretical Mechanics: Statics and the Dynamics of a Particle. By Prof. William Duncan MacMillan. Pp. xviii + 430. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1927.) 25*s.* net.

As the author of this book remarks, mechanics is a difficult subject not merely for the student but also for the race, as is evident by the fact that it came into existence two thousand years later than its allied subject geometry. In our time, however, it has also become a difficult subject for the textbook writer. Torn as he is between the practical necessity of retaining the framework and development of the Newtonian viewpoint and a desire to disavow the older conceptions of mass, energy, and force, this attempt to keep a foot in each camp is often more amusing than successful.

Admitting the difficulty, however, as more or less inevitable at the moment, this text-book is undoubtedly one to be recommended. Its style and its manner of presentation convey the impression that it is written by a good teacher. Wherever possible vectorial methods are utilised, and the fundamental principles are clearly and deliberately stated.

Part 1 deals with vectors and kinematical and geometrical concepts; Part 2 with statics of particles, rigid bodies, and deformable bodies, very clearly and easily developed; Part 3 with the dynamics of a particle, including a treatment of least action, Hamilton's principle, and Gauss's principle of least constraint. There are in all sixteen chapters, most of which are supplied with copious examples.

The British Journal Photographic Almanac and Photographer's Daily Companion: with which is incorporated The Year Book of Photography and Amateurs' Guide and The Photographic Annual, 1928. Edited by George E. Brown. Pp. 788 + 63 plates. (London: Henry Greenwood and Co., Ltd., 1928.) 2*s*. net.

THIS *Annual* continues to move in the direction of the character of other photographic annuals, though it remains unique as it preserves all its old features, except, indeed, that it is no longer an almanac. It contains twice as many pictorial photographs as last year's volume, and these are excellently reproduced in photogravure by the Vandyck Printers, Ltd. The special editorial article refers to the world-wide applications of photography, and other articles are on snapshots, amateur kinematography, and printing borders on development papers. The epitome of the year's progress, classified formulæ, tables, directories, legal details, and other useful information follow. It is worthy of note that the tables—optical, weights and measures, concerning exposure, and many other matters—are so numerous that for very many years it has been the custom to give a selection only of what would be possible and useful, but a classified and dated list is given of those published in past annuals that are not included in the present. The volume is practically indispensable for those who are in earnest in their photography, whatever the character of their work may be.

The Industrial Chemistry of the Fats and Waxes. By Prof. T. P. Hilditch. (Industrial Chemistry Series.) Pp. xv + 461. (London: Baillière, Tindall and Cox, 1927.) 18*s*. net.

THIS work is divided into ten sections, to each of which is appended a useful and up-to-date bibliography. An account of the chemical nature, analytical examination, and composition of fats and waxes is followed by a description of methods used in the extraction, refining, hydrogenation, and hydrolysis of fats. More specialised sections deal with the edible fat and soap industries; the use of fats in the manufacture of candles, illuminants, paints, linoleums, etc.; the production of glycerine; and the nature of fatty lubricants. The text contains a large number of useful tables and summaries, but illustrations and diagrams have been dispensed with. The book, written by an author possessing first-hand knowledge, provides a sound, workmanlike, and remarkably compact survey of an important field of applied organic chemistry, and it may be recommended to the student and research worker as well as to the industrial chemist.

Fogs and Clouds. By W. J. Humphreys. Pp. xvii + 104 + 96 plates. (London: Baillière, Tindall and Cox; Baltimore, Md.: Williams and Wilkins Co., 1926.) 18*s*. net.

CLOUDS have special importance to all who are interested in weather, now that forecasts are no longer based almost entirely on the movements of cyclones and anticyclones; we realise that the conditions are dominated by warm and cold parts—the boundary surfaces between air-masses at different temperatures; and so ability to recognise the clouds which mark these surfaces may give invaluable information. The different types of clouds are here systematically arranged, with a promising suggestion for an abbreviated nomenclature, and there are useful discussions of the physical processes involved, such as that of the mode by which 'the moon eats the clouds.' The author has also included a number of less familiar types, such as 'helm bars,' 'crest clouds,' 'cumulus boas,' and 'scarf clouds.'

Nature lovers will congratulate the author on the extent to which the photographs render the glory of a cloud-flecked sky; and there are excellent reproductions of lightning, of a rainbow, and of a halo with a parhelic circle.

Chambers's Encyclopædia: a Dictionary of Universal Knowledge. New edition. Edited by Dr. David Patrick and William Geddie. Vol. 10: Teinds to Zyrians. Pp. iv + 819. (London and Edinburgh: W. and R. Chambers, Ltd.; Philadelphia: J. B. Lippincott Co., 1927.) 20*s*. net.

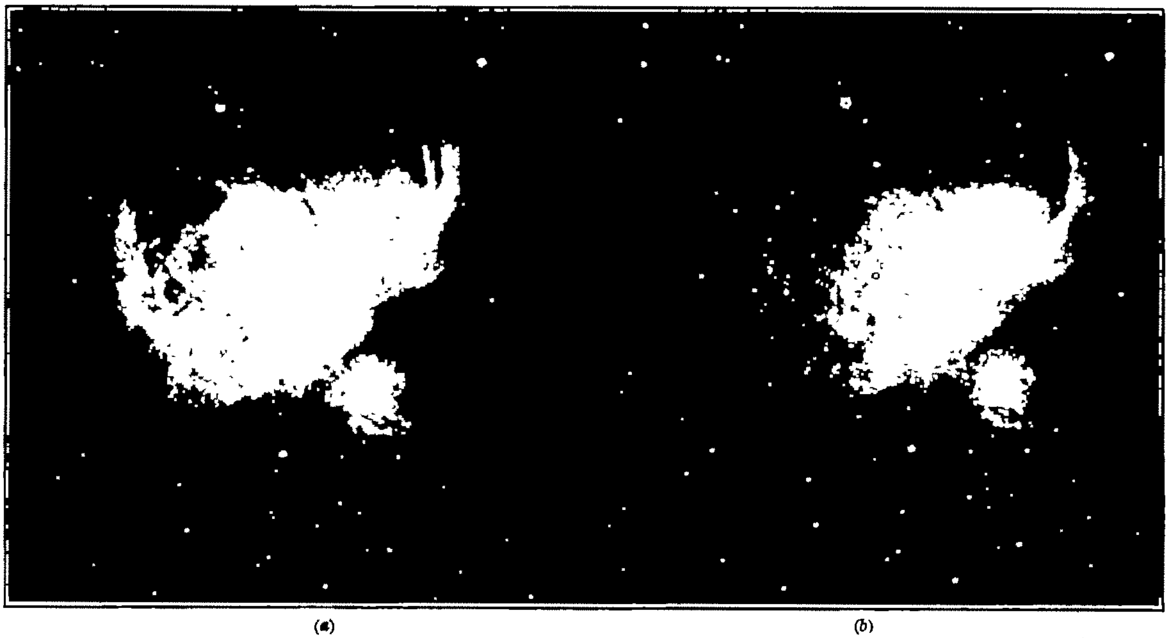
THIS concluding volume of the new edition of this encyclopædia has been revised up to the date of issue. As in the earlier volumes, there is a number of new maps, among which the orographical layer-coloured maps illustrating the article on the world-war may be mentioned for their special excellence. The completed encyclopædia forms an almost indispensable addition to modern works of reference. It is the custom in this encyclopædia to preface each volume with a list of the authors of only some of the articles: the others are anonymous. By way of criticism it is suggested that the authorship of the longer articles should be given, as is not always the case, while that of many short ones that afford no scope for original treatment could well be omitted if space is the chief consideration.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Distribution of Ionised Oxygen in the Gaseous Nebulæ.

THE suggestions made by Bowen in NATURE of Oct. 1 as to the probable origin of the well-known 'nebulium' doublet λλ5007, 4959, and of the strong radiations sometimes occurring at λλ3727, 9, have been confirmed by Prof. A. Fowler (NATURE, Oct. 29), and so generally accepted that it may not be premature to discuss the actual distribution of these radiations in the gaseous nebulæ on the assumption that the first doublet represents O III (twice ionised oxygen) and the second O II (once ionised oxygen). It is first of all important to note that there is no recorded evidence of the existence of the neutral atom of oxygen in the gaseous nebulæ, although some of the strongest lines, being in the extreme red, are beyond the reach of the apparatus usually employed. Neither can I find any references which support Bowen's statement that "the [gaseous] nebulæ are known to emit the well-known spectra of highly ionised nitrogen and oxygen." The most exhaustive study yet published of the nebular lines is that by W. H. Wright in *Lick. Obs. Pub.*, vol. 13, but although one line each is ascribed to neutral carbon and nitrogen, there is no identification with oxygen. On the other hand, the doublet λλ5007, 4959 is present in all cases considered, a total of 47 planetaries and the Orion nebula.



(a) (b)

FIG. 1.—Screened photographs of the Orion nebula. (a) λ3727; 47 min. exposure. (b) Hydrogen, 40 min. exposure.

It was noted in the case of the Orion nebula visually by Campbell at the Lick Observatory in 1893 that these lines, although invariable with respect to each other, varied considerably in intensity in comparison with the neighbouring line H_β. In the regions round θ Orionis, λ5007 was four times as bright as H_β, but as the slit was moved away from the trapezium region the comparative intensity changed until H_β was much brighter of the two. The same concentration of λλ5007, 4959 within the inner regions is also marked in the planetaries photographed with a slitless spectrograph appearing in the Lick volume already mentioned.

In 1905, Hartman attempted to isolate the doublet by means of a green screen and an isochromatic plate, but it is doubtful whether the hydrogen radiations H_β and H_γ were satisfactorily eliminated in the direct photograph of the Orion nebula he obtained, as my own results with greater precautions to get rid of these radiations did not give such an extended image, although the Huyghenian region came out very strongly, in this respect agreeing with Campbell's visual observations.

It is, of course, only to be expected that the doubly ionised state of the oxygen atom should be found principally in the regions of the nebula most influenced by the B type stars of the central region.

The distribution of O II in the Orion nebula is, on the other hand, remarkable both for its great extent and for its intensity. The image ordinarily obtained when an exposure is made with an undyed rapid plate is to a large extent produced by this radiation in the ultra-violet, as such a plate is practically insensitive to the radiations λλ5007, 4959. The only other important radiations in the sensitive range are the hydrogen radiations from H_γ to the head of the Balmer series, and as these decrease in intensity rapidly towards the ultra-violet, the main radiations are H_γ, H_δ, and H_ϵ. If, therefore, an exposure is made with an æsculine screen cutting off the ultra-violet beyond λ4000, an image is obtained which consists almost entirely of hydrogen radiations.

On the other hand, an exposure with a screen of thin nickel oxide glass, transmitting 70 per cent. at λ3800, but cutting off the visual spectrum except at the extreme red, gives an image consisting almost entirely of λλ3727, 9. This piece of work was undertaken some years ago by me at Harborne, and at Helwân Observatory with the 30-in. reflector, and the results obtained are here reproduced. There can be no doubt that the differentiation of the hydrogen and O II images has been actually attained, as there are marked differences of detail as well as of distribution in the two images. Take, for example, the long scimitar-like projection on the right-hand side of each photograph with its companion, or the star, indicated by a cross in Fig. 1, on the outskirts of the nebula, which is surrounded with hydrogen nebulosity, but is clear of O II.

It has already been remarked that the stars involved in the central regions of the Orion nebula are B type stars, and the radiations λλ3727, 9 exceptionally strong. As a matter of fact, these radiations are either very faint or absent altogether in many of the planetary nebulæ, where the stars are almost invariably O type of much higher temperatures, although a radiation of shorter wave-length at λ3426 is often present. A conspicuous radiation at λ3869, as yet unidentified, sometimes appears in place of λ3727, although both are present in a few cases.

A comparison of the intensities of λ5007 (O III) with λ3727 (O II) in the list of planetaries given by Wright (*loc. cit.*) brings out certain features of interest. The spectrum of N.G.C. 40 is unique, for although the slitless quartz spectrograph shows a conspicuous image at λ3727 there is no image at λ5007, but there is a trace of this radiation in the slit spectrograph exposure.

In three other cases (I.C. 418, N.G.C. 6720, and B.D. 30° 3639) λ3727 is brighter than λ5007. In ten instances λ3727 is absent altogether, with a trace only in two cases, altogether about 25 per cent. of the whole. In nine objects also λ5007 is ten times the intensity of λ3727, so it appears that the conditions favourable for the continuous existence of O II in any comparative quantity are absent in many planetaries. In all the planetary nebulæ the governing factor is undoubtedly the surface temperature and physical condition of the nuclear stars. Thirty of these stars are bright enough to yield a spectrum, and all these show the characteristic extension into the extreme ultra-violet denoting O type stars. Half of them contain bright bands, the other half are absorption spectra. There seems, however, to be no correlation between these divisions and the presence or absence of λ3727.

The Affinity of Different Types of Enzyme for their Substrates.

IT is well known that as the concentration of substrate molecules is increased, other conditions being kept constant, the rate of catalysis of a reaction by an enzyme reaches a maximum value. On the view that the enzyme-substrate complex is a chemical compound, this is due to the combination of every enzyme molecule with the substrate or its products; on the theory that the union is adsorptive, it is due to saturation of the enzyme surface. On either hypothesis the substrate concentration at which half the maximum velocity is reached furnishes a measure of the affinity between enzyme and substrate. If, as is often the case, the law of mass action is followed, it is, of course, the dissociation constant of the enzyme-substrate compound, and the reciprocal of the affinity constant.

I have collected from the literature such apparent dissociation constants for 44 enzymic reactions. When these are expressed in molar concentrations, the enzymes fall fairly sharply into three groups. Group 1, of low affinity, includes the hydrolytic enzymes acting on crystalloidal substrates, and also yeast carboxylase and liver catalase. Ten of these enzymes, catalysing 21 different reactions, give dissociation constants ranging from 0·003 M up to at least 0·7 M. Their affinities for substances related to their substrates which inhibit the reactions are of the same order of magnitude, but on the whole less. Two hydrolytic enzymes, bone phosphatase and liver lipase, yield values at present undetermined, but less than 0·003 M and 0·005 M respectively.

Group 2, of medium affinity, consists of the enzymes which hydrolyse colloidal substrates, namely, the proteins and higher polysaccharides. The rather dubious dissociation constants for these substances mostly, if not all, lie between 5 per cent. and 0·1 per cent., or, taking probable molecular weights, in the neighbourhood of 10^{-4} M.

Group 3, of high affinity, consists of the only oxidising-reducing enzymes other than catalase so far studied from this point of view. The values are:

Plant peroxidase . .	5×10^{-6}M	[Willstatter & Weber[1]].
Milk xanthine-oxidase	$<3\times10^{-6}$M	[Dixon and Thurlow [2]].
Yeast oxygenase .	$<6\times10^{-7}$M	[Warburg[3]].

The substrates were hydrogen peroxide, xanthine or hypoxanthine, and oxygen, respectively. It should be added that xanthine oxidase also slowly catalyses the oxidation of acetaldehyde, but in this case the apparent dissociation constant is of the order of 1 M. In the case of laccase, the concentrations of guaiacol giving half the maximum velocity vary with *p*H between about 0·1 M and 0 003 M [Fleury [4]]. But laccase is probably a mixture of enzymes including peroxidase, in which case Willstatter and Weber's results make it unlikely that such observations furnish a measure of enzyme-substrate affinity. Biological surfaces which act as catalysts of oxidation, but cannot be brought into colloidal solution, and are, therefore, probably best not included under the designation of enzymes, yield apparent dissociation constants covering a wide range.

While the moderately high affinities of the amylases and proteases may be regarded as an adaptation to the colloidal nature of their substrates, it seems likely that the very high affinity of the oxidases is due to a real difference in the mode of their union with their substrates and that of other enzymes.

Pleochroic Haloes and the Age of the Earth.

DR. LOTZE offers the suggestion, in NATURE of Jan. 21, that the effect of the alpha ray in promoting, according to Mügge, "isotropy in minerals, loosening of the crystal lattice, and alterations in cohesion," would account for the unexpectedly large radius of the inner ring of palæozoic uranium haloes.

The stopping power, as all know, is dependent upon the atomic weight of the atoms encountered (Bragg and Kleeman). The density of the medium is therefore involved; and I assume it is to changes in this, brought about by the rays themselves, that Dr. Lotze refers his suggested explanation.

Now the observed discordance of the radius of the inner halo ring with the ionisation curve for uranium and its derivatives is more than 10 per cent. of the estimated radius (*Phil. Trans.*, 217, pp. 51-79). Can the changes which Dr. Lotze postulates be responsible for so great a reduction of density? It seems very improbable. If this considerable loss of density existed, we would expect some optical indications of its existence. But nothing abnormal, compared with the other halo rings, is visible.

---

[1] Willstatter and Weber, *Ann. Chem*, 449, p 156; 1926.
[2] Dixon and Thurlow, *Biochem Jour*, 18, p. 976, 1924.
[3] Warburg, *Biochem. Zeit.*, 189, p 354; 1927
[4] Fleury, *Jour de Pharm. et Chim*, 8, p 105, 1925.

Dr. Lotze does not specially refer to the emanation halo. In this case there is a single steep curve of ionisation rising to more than half the height of the crest responsible for the inner uranium ring. That is to say, rather more than half the ionisation intensity is operative in the formation of the emanation ring. Moreover, these emanation haloes are often of exceptional delicacy of definition and in the mica of Ballyellen are abundant. But no outward displacement of these rings is observable: but rather there is a tendency in the opposite direction—very slight, it is true.

Again, in the case of the thorium halo, the intensity of the ionisation upon which the effect should depend is about half that of the first uranium ring, but no irregularity is detectable (*loc. cit.*).

Papers in the January and February numbers of the *Philosophical Magazine* of the current year, by Dr. J. H. J. Poole, deal with a theory of the mode of formation of haloes in biotite, which should be considered in connexion with Dr. Lotze's suggestion. According to this theory, the formation of the halo in biotite is due to the decomposition, by the alpha ray, of the water which enters into the composition of the mica. It is assumed that the liberated and ionised oxygen combines with the ferrous iron present, thereby deepening the colour of the mica. That this theory, or some modification of it, adequately accounts for the genesis of the halo is, I think, very probable.

Now, variations in the density may attend these chemical changes, for it is possible that a part of the hydrogen might gradually escape by diffusion. At first sight this might seem to support Dr. Lotze's theory. But it is easy to show that the loss of the whole of the hydrogen would not suffice to reduce the specific density by as much as one per cent. This very probable theory of the inner mechanism of halo-formation therefore gives no support to Dr. Lotze's suggestion.

Lura Vopo Vir Can Utriet.

EVERY now and then a fresh attempt is made to solve this cipher attributed to Roger Bacon in the "Epistola de secretis operibus artis et naturæ et de nullitate magiæ" (see for example, NATURE, Sept. 4, 1926, p. 352). These words have no manuscript authority whatever; they appear for the first time in an edition of the "Epistola" printed in Paris in 1542 from a poor MS., and seem to be due to an attempt to reproduce the text before him by the editor, Orontius Finé. The passage reads thus:

"Sed tamen salis petræ LVRV Vo Po Vir Can Vtriet sulphuris et sic facies tonitruum . . ." (f. 52). All later printed versions are corrected from this.

Only two manuscripts of this part of the "Epistola" are known—both in the British Museum, Harleian 3528 (1) and Sloane 2156 (2). A third at Quaracchi, of which I have obtained photographs, leaves a blank where the cipher should be. As will be seen from the reproductions (Figs. 1 and 2), the cipher was originally written in Greek characters, which in the course of two centuries of copying have become entirely transformed. It is probable that if any cipher was used at all, certain of the letters were altered to those immediately preceding or following them, for example, blohkmkb—alchimia.

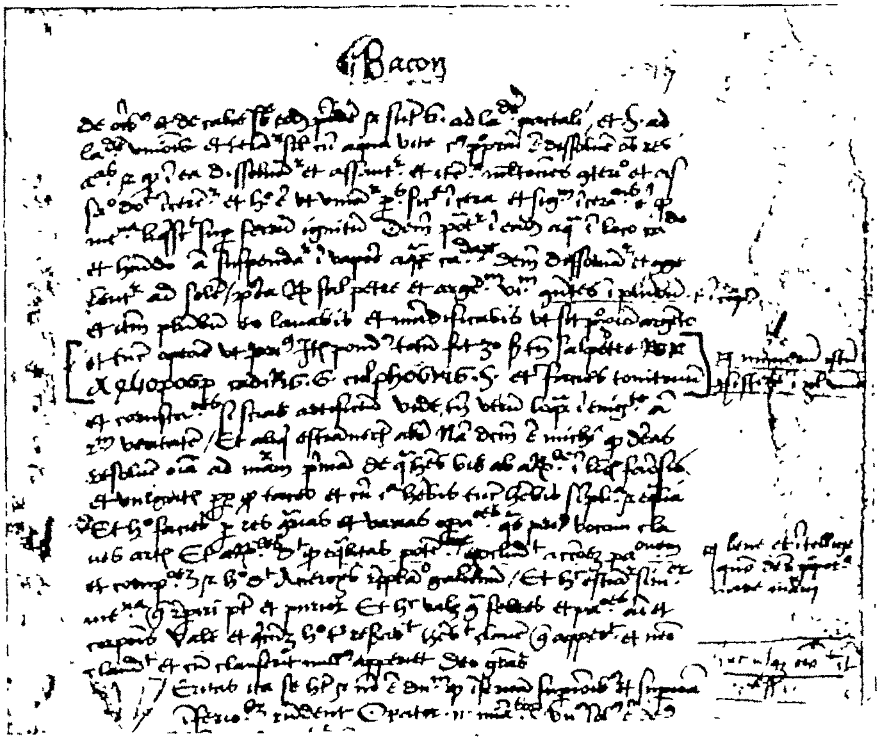

FIG. 1.—Harleian Manuscript. The passage containing the cipher is marked 1.

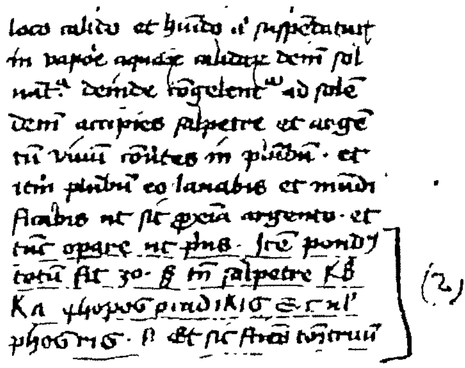

FIG. 2.—Sloane Manuscript. The passage containing the cipher is marked (2)

The relevant words in these reproductions are:

"Item pondus totum sit 30; set tamen salpetre . . ." The next signs read K 6, K 7—the K may be R. Prof. Minns, who has kindly studied these photographs, writes that the following group of six signs may suggest *ανθραξ*; the sixth sign is, however, the number 6, which with another 6 and the final 5 make up the 30 of the text. The þ following the group does not suggest any meaning. The following group of seven letters is read as salikis, followed by 6. The last group is read sulphouris, 5. It is obvious that this first attempt at reading the cipher is unsatisfactory, and as the "Epistola" must be reprinted with Bacon's alchemical works, I should be grateful for any help that can be given. Brewer in 1859 read No. 2 as KB/KA/φhoþos þcaδιαι ε.Γ. vel PHOSRIS. 8.,

Another interesting question is the equation of LVRV Vo Po, etc., to the letters of the Greek as a help to the reconstruction of the original passage.

The Pharmacological Action of Chloralose.

Chloralose was introduced some years ago by Richet for experiments on animals. The chloralose used in our experiments was obtained from Messrs. Baird and Tatlock, Ltd., but its origin is unknown. We have been informed that it is prepared by heating an anhydrous mixture of chloral and glucose at 100° C. for about one hour. The residue is treated with a little water and then boiling ether, and the toxic isomer, parachloralose, is eliminated by crystallisation. The formula is $C_8H_{11}O_6Cl_3$.

When a solution of chloralose saturated at 40° C. is injected intravenously into the decerebrate cat, we have observed an extraordinary action on the nerves. On stimulation of the splanchic nerve, the normal rise of blood-pressure is increased to an almost incredible degree. Repeated injection of 10 c.c. of the solution at intervals results in still further increasing the rise.

Its action on the somatic nerves is apparently of an opposite nature; for example, stimulation of the sciatic and anterior crural nerves gave no reflex results, thus demonstrating an inhibitory effect.

The full effect of chloralose in the respects mentioned is not manifested immediately. There is a gradual exaggeration of the rise with the lapse of time, the maximum result being obtained approximately thirty minutes after the injection.

This remarkable effect of the increase of the rise of blood-pressure due to stimulation of the splanchnic nerve is not seen if clips are placed on the adrenal veins. It is thus evident that the action of the drug is through the medium of the adrenal bodies, and it seems likely that it is that part of the rise of blood-pressure normally due to liberation of adrenin which is increased by the action of chloralose.

When the semi-lunar ganglia on both sides are removed and the fibres to the adrenal bodies are stimulated, the rise of blood-pressure is very markedly increased by the injection of chloralose into the adrenal bodies. Thus it appears we have in chloralose a marked stimulant to the adrenal bodies, and the action appears to be on a local mechanism consisting of the gland itself, and the nerve fibres reaching it from the semi-lunar ganglia.

Intravenous injection of a mixture of chloralose solution (saturated at 40° C.) and adrenin (1 in 100,000) causes the ordinary transitory rise of blood-pressure obtained by injection of adrenin alone to be converted into a large and long-sustained rise of blood-pressure. A similar curve is obtained when adrenin is administered to a decerebrate animal under chloralose.

It has been suggested to us that this 'stabilising' of adrenin action by means of chloralose may be of therapeutic value.

Dug-out Canoe in Algoa Bay.

With regard to the recent correspondence in Nature on the derelict canoe washed ashore in Algoa Bay, I have now received information from Lieut.-Col. M. L. Ferrar, Chief Commissioner, Andaman and Nicobar Islands, that it was reported in October 1925 that the sailing ship *Sree Shanasakthi* picked up three Nicobarese who were found clinging to a submerged canoe, which would have been of the ordinary size, holding six to eight people. These men belonged to Lapati, Car Nicobars. In the Albany Museum, Grahamstown, there are pieces of pumice from the Krakatoa eruption, that were washed ashore in South Africa; they have been preserved with all the barnacles and seaweed adhering, just as they arrived. I saw the Port Elizabeth canoe shortly after it had been pulled out of the water, and the encrusting material was identical in kind, showing both had been submerged for the same time, under similar conditions. Some part must have been above the sea for them to have caught the monsoon wind that drove them across. If the boat is from Car Nicobars, then it took sixteen months to come to South Africa, and somehow I think that four months is more likely correct. I am still inclined to place the origin in the Mergui Archipelago, because of the spoon-shaped fore-foot, and general shape.

The Two Calories.

The suggestion made by Dr. Russell in his letter in Nature of Feb. 4, that the kilowatt hour with its multiples and submultiples is the best unit of heat, is not new. Some years ago Ostwald proposed the unit of a kilojoule, and recalculated all the thermal data to the new unit. The figures will be found in his "Grundriss der allgemeinen Chemie," 1909. The reason why such a unit is not adopted in thermochemistry is that all the data would then depend on each redetermination of the mechanical equivalent of heat. The accuracy with which the latter is known probably does not, as yet, exceed one in a thousand, and thermochemists prefer not to have an error of this magnitude involved in determinations which are claimed to have an accuracy of one in ten thousand.

Eyeglasses and the Microscope.

With reference to T. H. T.'s suggestion (Nature, Jan. 28, p. 137) for dealing with eyeglasses while using the microscope, I find it quite sufficient to remove the cap from the eyepiece of the microscope; this allows the eye to approach to the right distance and at the same time keep the vision corrected for astigmatism. Of course with modern students' microscopes, which usually are not fitted with eye caps, this cannot be done; and astigmatism has to be put up with.

T. J. Briant.

The Bicentenary of John Hunter.

By Sir ARTHUR KEITH, F.R.S.

CONSIDER for a moment the unenviable position of John Hunter's two executors in the year 1793—his nephew Dr. Matthew Baillie and his young brother-in-law, Mr. (later Sir) Everard Home. Hunter's sudden death on Oct. 16, 1793, in his sixty-sixth year, left on their hands a huge establishment running from Leicester Square to Charing Cross Road—just to the south of the site now occupied by the Alhambra Music Hall. The income of the establishment had suddenly ceased; a sum of more than £10,000 a year was needed to keep it going. A brief search showed them that the place was in debt; bills had to be met. Hunter's carriage 'blood-horses' and coach had to go; Mrs. Hunter, brilliant and fashionable, had also to part with her coachman, her carriage, her horses, and sedan chair. Pictures, books, furniture had to be sold to provide Mrs. Hunter and her daughter with a modest shelter in Brighton. The weekly wage bill had to be reduced; the staff, numbering more than a score, was reduced at a stroke to one—Mr. Hunter's young museum assistant, William Clift.

FIG. 1.—The statue of John Hunter, executed by Weekes and erected in the Royal College of Surgeons, London, by public subscription in 1858.

What was to be done with the Museum which Hunter had erected in the yard or garden of his premises? On this treasury he had lavished every sovereign he could earn or borrow, and every hour he could steal from practice, hospital, and sleep. It was the harvest of an intense lifetime. After seven years of 'lobbying,' the two executors succeeded in persuading a government in search of money to wage successful war with France, to buy Hunter's museum for £15,000. The collection was handed over to the Corporation of Surgeons in 1800; that body obtained at the same time a new charter, became the College of Surgeons, and established itself and its museum on the south side of Lincoln's Inn Fields—where both still flourish.

The two executors continued to believe in Hunter's greatness, as may be seen from the following quotation taken from the issue of the College calendar for the present year:

> "In the year 1813, Dr. Matthew Baillie and Sir Everard Home, Bart., executors of John Hunter, 'being desirous of showing a lasting mark of respect' to the memory of the late Mr. John Hunter, gave to the College the sum of £1684 : 4 : 4, three per cent. Consolidated Bank Annuities for the endowment of an annual oration, to be called the Hunterian oration, and to be delivered in the theatre of the College on the 14th of February, the Birthday of John Hunter, by the Master, or one of the Governors for the time being, or such other member of the Court of Assistants as should be appointed—such oration to be expressive of the merits in Comparative Anatomy, Physiology, and Surgery, not only of John Hunter, but also of all such persons as should be from time to time deceased, whose labours may have contributed to their improvement or extension."

The first oration was given in 1814 by Sir Everard Home; last year it was delivered by the president of the College, Sir Berkeley Moynihan; this year Sir Holburt Waring is Orator, and will take the opportunity of measuring the debt which modern surgery owes to discoveries made by chemists and by physicists. Hunter's two executors were interested parties; were they justified in launching on succeeding generations this act of Hunter worship? Is Hunter's memory being kept alive by a species of 'artificial respiration'? Many younger surgeons would return a frank affirmative; what Hunter thought and did, they hold, has no bearing on the surgical problem of the twentieth century. With whom lies the truth? With the executors, or with these modern critics?

Before seeking to measure our indebtedness to Hunter, let us first inquire how a youth—the youngest of a family of ten, bred on a bleak upland farm some eight miles southward of Glasgow, succeeded in establishing himself in London as the leading surgeon of his day. John Hunter's career was determined in 1736; "Jockie," then a spoiled boy of eight, was running wild at home, while his brother William, ten years his senior, had finished with the University of Glasgow and was thinking of the Church as a career. It was in this year that a young practitioner—William Cullen by name—settled in the neighbourhood. In due time he was to become the great Dr. Cullen and hold in medicine much the same position as his contemporary Samuel Johnson held in literature, but in the meantime we are concerned with him merely as medical attendant on the Hunter family. He recognised William's ability; took him into his house as pupil-apprentice; put him in touch with the medical problems of the time, and showed him how the leading minds of Europe were seeking to solve them. We are indebted to Cullen for the medical Hunters.

FIG 2.—Portrait of John Hunter, from Sharp's engraving of the original picture painted by Sir Joshua Reynolds in 1788, when Hunter was sixty years of age.

William Hunter's ambition was thus fired; in October 1740 he visited London and found a pretext for not returning to Scotland. There were great hospitals in London then, but no medical schools were attached to them as is the case now. Such schools as existed were in private hands. William established one in Covent Garden, laying himself out for practice at the same time. He was careful in dress, suave in speech, and cultured in manner; he had an eye on Court and on the main chance; he was a scholar, a brilliant teacher, kept himself closely in touch with the best that was being thought and done in medical Europe, and made observations for himself at first hand.

In October 1748, William found his school in a prosperous state; his dissecting room was crowded; the preparations which he had made and preserved to illustrate his lectures began to form an imposing museum. His youngest brother, John, although twenty years of age, was still idling at home; he had grown into a short, thick-set fellow, with sandy hair and freckled face. William brought him to London and set him to work in the dissecting room. John took to the life as a duck takes to water; he had hands and could use them; he never really cared for books; he preferred to decipher the hieroglyphics of life at first-hand; he chose to register his discoveries in museum jars rather than in printed pages. It was only when he turned lecturer that he was compelled to reduce his observations, thoughts, and experiments to words. He was careless of dress, unconventional in manner, and uncompromising in speech. An unceasing search into the nature of life became his religion. He was resolved to win on merit; and in the long run, sheer merit was victorious. Cullen launched William on the sea of medicine, and in due course William launched his brother John—now the subject of seventy-four Hunterian Orations.

So I come back to my main question: What did Hunter do for medicine that we should continue to be mindful of him? Great men, as a rule, are so easily labelled—Jenner, Hunter's pupil, discovered the efficacy of vaccination; Charles Bell demonstrated the action of spinal nerves; Marshall Hall discovered reflex action; Lister, antiseptic surgery. In not one of these cases is the label adequate, but the public demands that its great men must be ticketed. There is no tag for John Hunter; to do him justice we must give him a hundred.

It has been said that Hunter was the founder of scientific surgery. If by this is meant that surgery will become a science only when all the secrets of life have been revealed and mastered, then Hunter has a just right to such a title. For the obsession of his life was the discovery of the mechanism of living matter; he perceived that life was the same in all its forms; an organised blood clot in a patient in St. George's Hospital was for him the same thing as the hydra which he grew in his vivarium at Earl's Court. He applied the same method of study to both. He knew nothing of oxygen, oxidation, or of the chemical nature of combustion, but he measured the 'amount of life' by the 'vital' heat generated, using the most delicate thermometer obtainable, to give him a standard for comparison. He knew nothing of those living units we now call cells or corpuscles; he measured the processes of 'simple life' in the mass. He subjected it to all degrees of temperature and noted its reactions.

In this way Hunter tried to get at the secrets of that reaction of living matter which is called inflammation. He used his thermometer to tell him what was happening in the hibernating hedgehog, his beehives in winter, and the trees of his garden when frost was deep in the ground. He realised to the full that if we are to understand life we must first study growth, and that of all the tissues of the animal body, bone was the one which best lent itself to an exact inquiry. He carried out an experimental study of the growth of bones, extending over many years, in fowls, pigs, asses, and deer; he used the modern methods of vital staining and of experimental operation. He regarded antlers as bony tumours; he sought to understand how Nature produced them and particularly he desired to discover the secrets of the bloodless operation by which she removed them annually—without fee. Living matter, by itself, had mastered the art of healing; if men were ever to become surgeons they must learn their art by studying the surgical ways of living matter. That was Hunter's message to his day and generation; for this reason he turned experimental embryologist, experimental botanist, experimental zoologist, experimental physiologist, experimental pathologist, and experimental surgeon. What he did and what he thought can never cease to be a source of inspiration to those who inquire at first hand, for the problems he sought to solve are still those which envisage us—the basal problems of life.

Why, then, do the younger surgeons of to-day neglect Hunter or brush him aside as out-of-date? It is because of the unbounded success of Lister's discovery; the Listerian revolution has led them to concentrate their whole attention on the cleanliness of their wounds and the technique of their operations. Their attention is occupied with the organisms which may invade wounds and they forget a fact ever present in Hunter's mind—that the powers of healing are resident in the living flesh. No one who notes what is happening now in the most progressive lines of biological inquiry—experimental embryology and experimental biology, as represented by tissue culture, tumour grafting, transplanting of living organs and parts—can fail to see that after a century and a half we are again returning to the Hunterian outlook and the Hunterian methods of approach.

Hunter's published works are contained in six volumes—the four volumes which are included in Palmer's edition (1837) and the two precious volumes of "Essays and Observations" published by Sir Richard Owen in 1861. A study of these volumes shows how dangerous it is to say wherein Hunter was wrong or mistaken; he made many grave errors of inference—none of observation. But in the majority of instances time has proved that it was not Hunter who was in the wrong, but his editors.

There is one aspect of Hunter's life which his annotators have refused to mention, or if they have alluded to it, explained it as an aberration of a great mind. The truth is that Hunter's inquiries had made him a pagan; he could not harmonise what he found in the realms of Nature with what his inquiries revealed to his own eyes. He silently and resolutely thought and wrote as if the book of Genesis had never been in existence. The last paper he ever penned was "Observations on the Fossil Bones presented to the Royal Society by His Most Serene Highness the Margrave of Anspach." In this paper the council of the Royal Society was alarmed to find that Hunter, in order to explain certain changes, postulated "thousands of *centuries*," and ultimately succeeded in getting the estimate reduced to thousands of *years*, thus bringing the estimate within the limits of Biblical chronology. In the meantime Hunter died, and his brother-in-law, Sir Everard Home, readily sanctioned the desired change. Even Sir Richard Owen in 1861 is an apologist for Hunter's heretical beliefs. In the 'advertisement' to "Essays and Observations" he wrote;

> "Some may wish that the world had never known that Hunter thought so differently on some subjects from what they believed, and would have desired him to think. But he has chosen to leave a record of his thoughts and, under the circumstances in which that record has come into my hands, I have felt myself bound to add it to the common intellectual property of mankind."

There would have been no record left if Sir Everard Home had had his way. That any record was preserved at all of Hunter's real thoughts is due to Owen's father-in-law, William Clift. Home burned Hunter's original manuscripts, the usual explanation being that he had pilfered from them. A close study of the conventional character of Sir Everard Home and of the circumstances which surround this infamous act of vandalism have convinced me that the accepted explanation is not the true one. Home shared implicitly in the religious beliefs of his time and never doubted that by destroying all evidence of Hunter's heretical convictions he was performing an act of piety on behalf of the world in general and for the memory of his brother-in-law in particular. The world has still much to learn from John Hunter.

British Association Expedition to the Great Barrier Reef.

By Dr. C. M. YONGE.

MARINE biology has advanced greatly of recent years. It is becoming quantitative in its methods, beginning to demonstrate cause as well as effect, while, as the result of co-ordinated research by plankton workers and chemists, the full story of the annual cycle of life in the sea is gradually being elucidated. Practically all this work has, however, been done in temperate seas, and the extent to which similar conditions prevail in tropic waters is entirely unknown. Here is a great and open field for the application of modern scientific methods and one in which a rich harvest cannot fail to be reaped. Hitherto, opportunities have been lacking; there are no big marine laboratories in the tropics, while deep-sea expeditions have only been able to make isolated observations.

This long-desired opportunity has at last been provided by the Australian Great Barrier Reef Committee, which two years ago invited Great Britain to send out an expedition to make a thorough biological investigation of the Great Barrier Reef of Australia. The organisation of this expedition was undertaken by the British Association at the recent meeting at Leeds, and a committee, consisting of members of the Sections of Botany, Geography, Geology, and Zoology, to which were later added several Australian representatives, was instituted for this purpose.

If the necessary funds can be raised, the expedition will leave this spring, and work on the reef will be carried on continuously for at least a year. The leader of the expedition will be Dr. C. M. Yonge, Balfour Student in the University of Cambridge. Mr. F. S. Russell, of the Plymouth Marine Biological Laboratory, will be in charge of the plankton investigations and other work of the boat party for the first six months. Mr. Tandy, of the British Museum (Natural History), is expected to be the botanist, concerned especially with the calcareous algæ; and the Royal Geographical Society is considering how best to provide the services of a surveyor for the expedition. The full plan also includes a chemist and hydrographer, who will study the chemical and physical conditions of the sea water, while an experienced zoologist has expressed his willingness to take charge of the reef work. In addition, there is the promise of considerable assistance from the Universities of Brisbane and Sydney, and from the Australian Museum at Sydney; the British Committee lays the greatest stress on this, in view of the continuation of such studies in subsequent years.

With the exception of the work of the geographer, the investigations proposed will be purely biological. The geology of the reef has already received considerable attention from Prof. H. C. Richards, of the University of Brisbane, who has been the prime mover in all recent work on the reef. It is hoped that the surveying ship of H.M. Australian Navy will be able to assist in the accurate surveying and charting of the region where the expedition will work.

The plan of operations may be conveniently summarised under four headings. First, there is work on the reef, and this will include an ecological survey of the corals and their associated organisms, both animal and plant, their food and mode of feeding, their rate of growth, and their seasons of reproduction. Conditions on various parts of the reef, exposed to very different factors, will be compared and correlated with differences found in the plankton and the sea water. This work will be conducted by a 'reef' party of probably two zoologists and the botanist.

Closely connected with the above work will be an examination, as detailed as conditions will allow, of the bottom fauna and flora and the deposits, between the reef and the mainland and, so far as possible, on the outer side of the reef. For this purpose dredges and the Agassiz trawl will be used, and also quantitative grabs and bottom samplers. An important part of this work will be the determination of the zoning of life at increasing depths, information which is urgently needed for the proper working out of the contents of the bores made into reefs.

This work, and that of the third set of investigations, concerned with plankton and sea water, will be carried out from a powerful motor-boat which has been kindly offered, together with a smaller boat for work round the edge of the reef, by the Navy Yard at Sydney. The variations of the plankton—seasonally, diurnally, and at different depths—will be studied by means of samples taken with water-bottles, fine and coarse silk tow-nets, and stramin nets. Mr. Russell, who will have assistants, will employ the methods which have yielded him such excellent results in Great Britain, so that the findings will be directly comparable with those obtained in our temperate seas. A series of stations will be selected for this work, and water samples will be taken at the same time from which accurate determinations of temperature and salinity, of the nitrate, phosphate, silica, calcium, and oxygen content, and of the hydrogen-ion concentration will be made by the chemist. Variations in these will be correlated with variations in the plankton.

The fourth line of research will, it is hoped, tie together all the work into one connected whole. It will consist of a detailed study of the mode of feeding and digestion in the different corals, and of their food throughout the year. The relative extent to which corals depend upon plankton for food or are nourished by the unicellular algæ which live symbiotically in their tissues will be investigated. This is a matter of fundamental importance and one on which our knowledge is extremely scanty. The method of calcium deposition in corals, as a result of which the skeleton is formed, will also be studied.

Finally, the economic possibilities of the reef will receive thorough attention. At present there is an extensive trade in pearl shell and trochus, in bêche-de-mer and in turtles, and the possibility of increasing these by methods of cultivation and of establishing a sponge fishery—of native or, if feasible, imported sponges—will be examined. The commercial potentialities of the fisheries will be estimated so far as opportunities permit. The Great Barrier Reef is immensely rich in life and should prove a source of vast wealth if properly exploited, and for this a thorough biological survey is the essential preliminary.

Obituary.

Mr. R. A. Herman.

CAMBRIDGE mathematicians of the past forty years will have learnt with deep regret of the sudden death of Mr. Herman, of Trinity, on Nov. 29 last, at the age of sixty-six years. Versatile and skilful, Herman devoted to teaching powers that were ample to have made him one of the celebrated mathematicians of his time, and his monument must be sought in the multitude of his pupils who have won distinction for themselves.

Herman took the Tripos in 1882, and was described at the time as the last 'real' Senior Wrangler, for the Tripos was about to be divided, and the title, though surviving until 1909, depended after Herman's year on only the first part, the second part being a postgraduate examination. After gaining in due course a Smith's Prize and a Trinity fellowship, Herman went to Liverpool as professor, but he stayed there only two years, and returned in 1886 to Cambridge, where he spent the rest of his life. He was given the honorary degree of LL.D. at St. Andrews in 1920.

At the time of Herman's return, and until 1909, mathematical teaching in Cambridge was of two kinds: in theory the ground for the Tripos was covered by college lectures, but in practice success depended on the private coach. Herman served a full period of office as a college lecturer, and he was a University lecturer for many years, but it was as a coach that he became famous. Reputation in this field was difficult to acquire, but Herman had a genius for teaching which won its reward when J. E. Wright was Senior Wrangler in 1900, and from 1903 until 1909 one or more of his pupils, alone or bracketed, headed the list: of the last eleven Senior Wranglers, he coached nine.

For a few years after 1909, force of custom still sent the best scholars to be coached, but the new regulations put the premium on specialisation, and the use which Herman could make of his powers under the changed conditions was still uncertain in 1914. During the War he was engaged on various routine tasks; he lost his only son, reported missing and never heard of again, and suspense and grief affected his subsequent career. After the War he continued to read and to enjoy mathematics, but his diminished energy found sufficient scope in his University lecturing.

Herman was beyond question a great teacher, at once conscientious and inspiring, methodical and brilliant. His revision papers were miracles of thoroughness, and by means of weekly problem papers he imparted all that it was possible to impart of his own facility in the problem-solving that was formerly essential to distinction in Cambridge examinations. As a mathematician he was an artist to the finger-tips, scrupulously rigorous, little satisfied by a mechanical solution, and quick with praise when he saw beauty. There was no branch of Tripos mathematics in which he was not proficient, and there were many subjects in which his knowledge extended far beyond the range of any examination. He was an astronomer in a university where astronomers flourish, his only book was on geometrical optics, and he was an authority on the most difficult problems of discontinuous motion in fluids, but it was to differential geometry as investigated by kinematical methods that he was most devoted.

A teacher's fame is local and ephemeral, but so long as any of Herman's pupils are alive he will be remembered with gratitude and affection.

Mr. J. H. Durrant.

Through the death at his residence at Putney on Thursday, Jan. 19, of John Hartley Durrant, entomological science loses a worker who has long been known for his extensive knowledge, not only of the Microlepidoptera, but also of entomological literature and matters in general connected with taxonomy and nomenclature. Mr. Durrant was born at Hitchin on Jan. 10, 1863. He was one of the few remaining fellows of the Entomological Society of London who could date their association with that Society back to 1883, when he became a member. In 1886 he took charge of the late (the sixth) Lord Walsingham's extensive collection of Microlepidoptera at Merton Hall, Norfolk, and when this collection, which comprised some 260,000 specimens, was transferred, together with the Walsingham entomological library, to the British Museum (Natural History), he became a member of the scientific staff there.

Mr. Durrant was closely associated with the late Lord Walsingham in the preparation of the Microlepidoptera volumes of both the "Fauna Hawaiiensis" and the "Biologia Centrali-Americana," and he was personally responsible for the completion of the latter work after the transfer of the Walsingham library and collections to the British Museum. He was a most careful worker, and one has only to look at the manner in which the extensive synonymies given in the "Biologia" are drawn up, to be impressed by the evidences of painstaking care and sound judgment there exhibited. In an interleaved copy of the volume on the Microlepidoptera of the "Biologia Centrali-Americana," as well as in his note-books, there is also evidence that he was an accomplished artist, many of his sketches being remarkable for both their accuracy and their beauty.

Mr. Durrant was intensely interested in all matters concerning entomological nomenclature, and he was responsible, with Lord Walsingham, for the compilation of what are now familiarly known as the "Merton Rules." Herein is displayed such evidence of acute insight and sympathetic appreciation of the needs of the systematist as could only be manifested by minds accustomed to face and overcome obstacles inherent in a science that has made steady and comparatively rapid progress through many changes, during a period of nearly two hundred years, since its firm establishment by Linnæus. On the formation of the British National Committee on Entomological Nomenclature in 1913, Mr. Durrant fittingly became its first secretary, retaining that office until 1924.

Mr. Durrant was one of the foremost authorities in Great Britain on the Microlepidoptera, and always showed a keen interest in small moths of economic importance, even when outside the scope of his special work. He was particularly attracted to the Pyralid genus Ephestia, the species of which are injurious to various food-stuffs, and his knowledge of these destructive pests resulted in his association with Major-General Sir W. W. O. Beveridge in the "Army Biscuit Enquiry," a report on which was published in 1913, and, in consequence of the value of the results obtained, reprinted during the War by the Trustees of the British Museum. It has been asserted on good authority that improved methods of preparing and baking Army biscuits, adopted as the result of these researches, have resulted in the saving of a considerable sum of money annually.

For ten years Mr. Durrant was on the editorial board of the *Entomologist's Record and Journal of Variation*, and his extensive knowledge of obscure scientific literature was always at the service of his fellow-editors and the many others who consulted him. Well known to all who visited the Entomological Department at the British Museum, he was an equally familiar figure at the meetings of the Entomological Society, which he attended regularly until the last year or so, when failing health made him avoid venturing out at night. Although apparently a man of strong constitution, his strenuous activities in connexion with the work of the British Red Cross Society during the War, when he served with the Natural History Museum Section of the 31st London V.A.D., added to the loss of his only child during the same period, seem to have affected his health, and to some extent to have hastened his end. Of genial disposition, friendly to a degree, his warm greeting will long be missed by all who knew him, and not least by those who were most closely associated with him in his various activities.

W. H. T. T.

Dr. William W. Fyvie.

Through the death, from pneumonia, of Dr. W. W. Fyvie, at Aberdeen on Jan. 17, after a short illness, the science of physics, particularly in the branch of radio communication, has lost one who gave his best in her service; and his Alma Mater, whom he served throughout practically the whole of his graduate career, mourns a son who by his labours enhanced her prestige and brought honour to her name.

Dr. Fyvie was essentially an experimentalist. He showed his ability in this direction very early in his career, for when he graduated in 1904 he did so as the most distinguished graduate of his year in practical physics. Six months after graduation he joined the staff of the Natural Philosophy Department of the University of Aberdeen, then under the supervision of the late Prof. Niven. For some years, owing to his time being mainly occupied with the routine work of the Department, he had little opportunity of developing any particular line of research of his own. Gradually, however, he began to devote more and more time to the study of radio telegraphy. This interest was fostered by Prof. Niven, who had himself done much work in this subject in its earlier stages. As a result the Department became one of the then comparatively few stations permitted both to send and receive radio signals. The outbreak of the War put an end temporarily to their activities, but with the cessation of hostilities the work was again resumed.

The problem which interested Fyvie most at that time was that of telephonic reception, and his energies were turned towards finding the best method for accomplishing this end. Within more recent years he applied himself assiduously to the explanation of the variation of signal strength at sunrise and sunset, and to the problem of 'fading' in general. About twelve months ago he evolved a theory of 'fading' in terms of the interference of reflected waves which accounted excellently for a large number of observations, but he refrained from publishing it until he could satisfy himself of its applicability to all conditions, and he was still working actively on the problem when he died.

The loss of Dr. Fyvie will be felt by many generations of students, to whom he was always a popular and inspiring teacher; while those who knew him intimately, knew him for a man of sterling worth, always ready and willing to spend himself on behalf of his friends.

We regret to announce the following deaths:

Mr. Miller Christy, author of a "Handbook of Essex," "Birds of Essex," and other publications on the archæology of Essex, on Jan. 25.

Prof. J. L. Heiberg, of Copenhagen, the historian of Greek mathematics and natural science, a corresponding fellow of the British Academy, on Jan. 4, aged seventy-two years.

Prof. H. A. Lorentz, For. Mem. R.S., and Copley medallist in 1918, for many years professor of theoretical physics in the University of Leyden and one of Nature's "Scientific Worthies," on Feb. 4, aged seventy-four years.

Dr. T. Adrian Palm, who put forward the view that rickets is due to deprivation of sunlight so long ago as 1890, and was the author of contributions to medical literature on diseases and customs in Japan.

News and Views.

IN his presidential address to the fifteenth Indian Science Congress, delivered at Calcutta on Jan. 2, Dr. J. L. Simonsen outlined the early history of the Congress, the first meeting of which was held in 1914. Reviewing the present position of education and research in India, he found matter for congratulation in the advance of the spirit of research in the Indian universities, but deprecated the fact that, with few exceptions, the degree standard has been considerably lowered during the last few years. He attributed this change to the recent University Acts, which have transferred the detailed control of courses of study and standards of examination from the professorial staffs to bodies of laymen. In order to overcome the difficulty of coping with large numbers of students who regard a collegiate career merely as a stepping-stone to government appointments, Dr. Simonsen advocated the extension of Civil Service examinations to all grades in the clerical departments of government. Such a competitive system, although not free from defects, "would liberate the universities from their present thraldom and enable them to devote themselves to their true function, the advancement of learning."

IN the special section of his address, Dr. Simonsen directed attention to the importance of the study of natural plant and animal products. He instanced the work of Annett and his collaborators on the relationship of the alkaloidal content of poppy juice to the age of the plant and to external features, such as the nature and previous treatment of the soil. While commending work of this kind, he deplored the general neglect in India of the chemical study of natural products: "Is it presumptuous to suggest to the organic chemists of India that they should study intensively the unique wealth of material which lies at their door, and devote less time to the study of problems of theoretic interest only?" As an example of the value of collaboration between organic chemists and botanists, he alluded to the two grasses known as 'Sofia' and 'Motia'; although these are both classified as *Cymbopogon Martini*, Stapf, the first yields the valuable palmarosa oil, while the second gives a comparatively valueless ginger-grass oil. Dr. Simonsen suggested that a detailed botanical and chemical examination of the many Indian Cymbopogon grasses would probably lead to results as interesting as those obtained by Baker and Smith in their work on the differentiation of closely related species of Eucalyptus, and that such work might throw light on possible relationships between the chemical constituents of a specific oil and characteristics of soil and climate.

THE annual report presented on Dec. 8 to the Regents of the Smithsonian Institution of Washington recorded active progress in all departments, limited only by lack of funds. Thus more than thirty expeditions took the field, and among their chief results were the obtaining of first knowledge of Dutch New Guinea, one of the few unknown areas remaining on the earth's surface; an archæological and anthropological reconnaissance of Alaska, during which a plan of more intensive exploration was prepared; the collection from Tanganyika of some 2000 live animals combining interest to the public and scientific importance; the inauguration of a third solar observatory for the measurement of solar radiation in the eastern hemisphere; the systematic collection of mineral specimens from Mexico, of ferns from Jamaica, of natural history material from Haiti. This in spite of the fact that, as the report says: "Almost no unrestricted funds for field work were available, each expedition being separately financed either by the generosity of some friend of the Institution or through a co-operative arrangement with some other organisation whereby the costs and collections were shared. Such a programme of field work is of necessity haphazard."

IT is to be hoped that some increased support from the Government as well as from individuals may be the result of the conference of distinguished men of science and leaders of industry held at the Smithsonian a year ago under the chairmanship of Chief Justice William H. Taft. As an organiser and leader of work in pure science, and as the controller of the national collections in art and science, the Smithsonian fulfils a national duty. Its international services are appreciated in all civilised lands. During the past year the International Exchange Service handled 590,879 packages, an increase of 110,103 over the previous year's total. We note with more interest than sympathy that the Smithsonian still has hopes of re-starting the International Catalogue of Scientific Literature. The bibliographers who met at the International Institute seem to labour under no such delusion and are the more practical in consequence.

THE Manchester Geological Society was founded in 1838, and the earlier volumes of its *Transactions* contained a large number of important papers dealing with pure geology. In course of time, however, the Society devoted its energies more and more to mining matters, and eventually came to be one of the bodies incorporated in the Federated Institute of Mining Engineers. Not unnaturally, the people of Manchester and district continued to feel a desire for a local geological society; a proposal to form a geological section of the original society was not found practicable, and finally the Manchester Geological Association was founded as an independent body, but nevertheless in close touch with, and with the full benediction of, the older society, and the rooms and library of the latter at Queen's Chambers, 5 John Dalton Street, Manchester, were placed at its disposal on very liberal terms.

THE first number of the *Journal* of the new Manchester Geological Association has recently appeared. It includes a presidential address by Prof. O. T. Jones, and three detailed papers on various Carboniferous topics. Prof. Jones's address, entitled "The Foundations of the Pennines," is of high interest. By a series of ingenious deductions he arrives at the conclusion that this foundation must be chiefly pre-Cambrian, but the argument cannot be summarised in a few words. Father Waddington, S.J., dealing with the district round Stonyhurst, offers some trenchant criticism of the validity of the stratigraphical term Pendleside Series, both locally and generally. He shows that the only true Pendlesides are conterminous with the Bowland Shales of Phillips: the Pendleside Limestone, from which the group was named, lies outside it according to modern zonal work, and the name should be dropped altogether. Mr. J. W. Jackson describes the succession below the Kinder Scout Grit in North Derbyshire, and Mr. A. Bray deals with the carboniferous sequence in the Colne district. This publication gives evidence of much energy and enterprise on the part of the new society, which also conducts excursions to places of geological interest. We wish it a long and successful career.

THE impression of persistent stormy, mild, wet weather, with a preponderance of south-westerly winds over Great Britain since the severe frosts of last December, is reflected in the weather summary for January issued by the Meteorological Office as a supplement to the *Daily Weather Report.* This weather was due to an unbroken succession of depressions, the majority of which followed a north-easterly track outside the Hebrides, although a few moved nearly due east across the northern districts of Great Britain and dispersed on approaching an anticyclone over northern Europe. For dwellers in towns, where shelter from rain is so easily secured, and a few hours of strong wind afterwards suffices to give dry conditions under foot, this stormy type of weather is perhaps the least unpleasant at a time of year when anticyclones, if accompanied at first by clear skies, soon lead to dull or foggy weather. The sunny periods that normally occur with the arrival of polar air behind a retreating depression can give a monthly duration of sunshine well above the average, as the figures for last month prove. At Ross-on-Wye it was the sunniest January for at least fourteen years, and in many other parts of the country sunshine was also in pronounced excess. The general mildness, resulting from an almost complete absence of easterly winds, is shown by the mean temperatures for Kew, Aberdeen, and Valentia. Gales giving rise to gusts of upwards of 75 and even 80 miles an hour were unusually frequent. It was one of these, blowing from between west and north-west across the southern part of the North Sea, that was partly responsible for the disastrous floods in London on the night of Jan. 6.

THE excess of rainfall, which was the most remarkable feature of the weather for the month of January, appears to have been particularly marked in Scotland: at Stornoway the total of 268 mm. was the highest for January since records began there in 1873; and at Eskdalemuir, where 394 mm. fell, it was the wettest month of any since at least 1911. New monthly rainfall records were also made at various places in the Lake District. According to the *Westmoreland Gazette* of Feb. 4, the highest gauge of the Manchester Waterworks at Ullscarf registered 683 mm.; at The Wray, Grasmere, the rainfall was 620 mm., the previous highest being 575 mm. in February 1894; at Ambleside it was 595 mm. for the first 28 days, the previous record being 578 mm. in October 1903; at Windermere it was 421 mm.; and at Sedburgh it was 376 mm., the previous record being 369 mm. in August 1891; at Kendal it was 368 mm. for the first 28 days, the previous record being 319 mm. in October 1874. It is stated that January has easily passed all rainfall records for the first month of the year.

WE learn from the Kew Observatory that on Jan. 22, at about 6.12 P.M., a rather strong shock (which may be classed as an earthquake of intensity 5 on the Rossi-Forel scale) was felt in a small district including Hanley, Burslem, and Cobridge in North Staffordshire. A typical experience was that of Mr. F. J. Rathbone, of 321 Waterloo Road, Hanley, who wrote in a letter to the Meteorological Office: "I was lying on a couch in the living-room when there came a terrific 'Bump' and the whole house rocked. A large mirror, hanging over the mantelpiece (which I was facing), quivered violently, and light on the tiles round the fire-place shimmered rapidly, showing, I think, evidence of considerable disturbance at the foundations of the house. The shock was of very short duration, just as though a giant, using a mammoth hammer, had struck one mighty blow at the earth right under me: it might have been the result of a mine explosion or of a great subsidence of earth, but I have not heard of either of these latter happening." The brevity of the shock, its comparatively high intensity, and its small disturbed area (probably not more than a mile or two in diameter) indicate that the focus was small and at a very slight depth below the surface. They suggest that the tremors were caused by a small slip of the strata along a fault between Burslem and Hanley, a slip due to the withdrawal of the coal or of water from the mines. Such local earth-shakes are frequently felt in the mining districts of Great Britain.

MR. HOWARD CARTER has now dismantled the great canopic shrine in the innermost recess of the tomb of Tutankhamen and has examined the magnificent canopic chest and its contents. The result is shown in a series of illustrations which appear in the *Illustrated London News* of Feb. 4. In the accompanying letterpress, it is stated that the shrine was more than six feet in height and occupied a floor space of some five by four feet. It stood on a sledge. The canopy was supported by four uprights, and on each of the four sides was a statuette of a tutelary goddess with outstretched protective arms. Within was a canopic chest of semi-translucent alabaster standing upon a silver-handled sledge, and with a tutelary goddess carved in relief at each corner. The massive lid in the form of an entablature was fastened down with four seals attached to gold staples. Within were four receptacles with human-headed covers in alabaster sculptured in the likeness of the king. Within these again were the four exquisitely inlaid golden coffins which contained the viscera. These miniature coffins are exact replicas of the great gold coffin that enclosed the body of the king, but are even more elaborately inlaid in the feather design. Each bears the formula of the goddess and genius to which it belongs, and the texts pertaining to its protectors are engraved on the inside. It is interesting to note that owing to the carelessness of those who were responsible for erecting the canopy the protective deities were misplaced, Nephthys being placed on the east side where Selket should have been, and Selket on the south side in the place of Nephthys.

ON Feb. 2, Sir William Bragg gave the first of a course of lectures at the Royal Institution on "Faraday's Note-books," and dealt with ice and regelation. Sir William stated that the manuscript note-books of Faraday, which have not yet been published in full, show that in September 1842 he made a number of experiments on certain curious properties of ice. He had noticed that pieces of ice put together into a bowl may be melting as a whole, while at the same time they freeze the water just round their points of contact, and so join themselves together by solid bridges of ice. It is well known that ice is crystalline, and when a crystal grows, the new molecules have to take their places in correct alignment. Molecules of water are apt to hold back from crystalline arrangement, unless there is something to make the first step easy; a molecule near a piece of ice may be induced to join up to the crystalline structure already existing, and still more so if ice surrounds it. In the long arguments on glacier motion which took place in the middle of last century, much use was made of Faraday's experiments and ideas. But it was then believed that a single crystal of ice could not be distorted. It was not until 1890 that M'Connell showed that a single crystal of ice can be made to yield, certain layers of atoms sliding over one another. Just so with a metal; single crystals of various metals are remarkably pliable. A copper bar can be so made as to yield easily in one's fingers; yet if so moved once or twice, the single crystal breaks up into many small crystals and the bar regains the strength which is usually the property of a copper bar. The problem of the glacier closely resembles the problem of the flow of a metal. When this new fact is taken into account, the importance of Faraday's early work is more readily understood.

IN a Friday evening discourse on "Photosynthesis," delivered by Prof. E. C. C. Baly at the Royal Institution on Feb. 3, he stated that the conversion of carbonic acid directly into sugars and starches is one of the simplest of all the vital processes from the chemical viewpoint; yet, although it is known that it is effected by means of sunlight, there have been apparently insuperable difficulties in the way of its explanation. The greatest difficulty of all, perhaps, is that on any theory based on previous knowledge gained from the study of light reactions in the laboratory, the plant cannot absorb directly from sunlight sufficient energy for the synthesis to take place. Experiments in the University of Liverpool have shown that the explanation is in reality very simple; the definite factor is the existence of a surface on which the synthesis can take place. It has been found that if a coloured surface capable of absorbing carbonic acid is present, then on exposure to sunlight the carbonic acid is converted into sugars and more complex carbohydrates; the energy is supplied partly by the surface and partly by the sunlight. Thus photosynthesis of sugars is closely analogous to that achieved by the living plant, since it is known that a suitable surface exists in the leaves and, moreover, for the same area of surface the quantities of sugars produced in the leaf and in the laboratory are very similar. Furthermore, the same sugars are produced in both. Not only do these results offer an explanation of vital photosynthesis, but they also suggest that the key to the mystery of all vital chemistry has been found, and that this differs from the chemistry of man's achievement by virtue of the very large amounts of energy involved. The chemistry of life would seem to be one of high energy, whilst that of man's endeavour is the chemistry of low energy.

GREAT BRITAIN was the first to give a single authority the responsibility for the conduct of a national service of broadcasting. Since it started in November 1922, a large number of nations has adopted similar systems. The United States, however, is a notable exception, as it clings to systems based on private enterprise. In a paper on the design and distribution of radio broadcasting stations for a national service, read by Captain P. P. Eckersley to the Institution of Electrical Engineers on Feb. 1, the progress made is discussed and future possibilities are pointed out. It is estimated that 90 per cent. of the listeners in rural areas in Great Britain rely upon Daventry. A listener in an area close to the station, that is, within the 'wipe-out' area, can be guaranteed a continuous and perfect service, but those outside this area are liable to interference. The Swedish engineers have proved that waves travelling over forests attenuate much more rapidly than waves passing over water. The provision of alternative programmes more than doubles the value of a broadcasting service. It not only tends to satisfy a larger number of persons, but each programme also can be given artistic unity as there is no need to consider any compromise. Telephone lines have proved most valuable in this connexion, and probably give the best solution for interlinking distant stations. The British Broadcasting Corporation, in conjunction with the Marconi Company, is considering the feasibility of short wave transmission. Many technical problems are discussed in the paper, the low power choke-modulation methods being shown to be the most satisfactory. Since it started, the performance of 5 G.B. has given every satisfaction. The B.B.C. is at present engaged in considering methods of improving the service.

THE electrodeposition of nickel, silver, and gold were amongst the earliest applications of electricity to practical purposes. Recent researches have not only greatly speeded up the times required for the processes, but have also produced a far superior type of deposit. In addition, many new metals are now being deposited on a commercial scale, several of which have special valuable properties. A thin layer of zinc or cadmium protects steel from corrosion. Tin produces a silver white surface, and is used for improving the appearance of a metal. The metal, however, which is most experimented on at present is chromium. Its most important properties are its great hardness and its ability to keep bright and clean for long periods. Stainless steels and rustless irons are indebted to this element for their freedom from tarnish. In the *Electrical Review* for Jan. 13, S. Wernick gives a useful survey of the applications, properties, and the methods of deposition of chromium. It appears that chromium gives the hardest deposit that has yet been produced, being harder than hardened steel. Chromium plate has been found useful in prolonging the life of steel gauges. It has a faint bluish tinge, but takes a brilliant polish, the colour being somewhat similar to polished aluminium. The various solutions used for the deposition generally consist of chromic acid with the addition of a salt. A high current density is employed, and the temperature of the bath should be maintained at about 50° C. The heavy current rapidly heats the bath, so water cooling by lead pipes is necessary, and the rapid evolution of hydrogen produces an objectionable chromic acid spray in the atmosphere. Lead forms a useful and insoluble anode. The present cost of chromium plating is several times greater than nickel plating. Before long a standard specification will doubtless be agreed on, and chromium plating will become a commercial operation.

THE example of Mr. Charles Enderby, who a hundred years ago owned a fleet of sealing vessels sailing from the Thames for Antarctic waters and encouraged his captains to combine discovery with commerce, is now being followed by Mr. Lars Christensen, of Sandefjord, Norway, one of the leaders in modern whaling enterprise. One of Mr. Christensen's whale-catchers, the *Odd I.*, made a most successful dash into the Antarctic west of Graham Land in January 1927, when she reached and circumnavigated Peter I. Island, which had previously only been sighted from a distance by its discoverer, Bellingshausen, in 1821, and by Charcot in 1912. The island was photographed from all sides, and attempts were made to land on it at several points, but no beach could be found beneath the vertical cliffs of volcanic rock which alternate with glacier faces to form its coast.

IN September 1927, Mr. Christensen dispatched a small sealer named the *Norvegia*, under the command of Capt. H. Horntvedt, with a scientific staff of four, including Prof. Olaf Holtedahl and Dr. O. Olstad, for a scientific expedition in sub-Antarctic and Antarctic waters. The *Norvegia* reached Bouvet Island in the South Atlantic on Dec. 1 and landed upon it. The scientific interest of this feat lies in the fact that from its discovery by Bouvet in 1739, doubt and mystery have surrounded the island. Cook and Furneaux searched for it in vain in 1772; Cook again failed to find it in 1775, and although Enderby's sealers reported the island, on which they landed, in 1808 and 1825, Sir James Clark Ross sought for it without result in 1843, and Lieut. Moore, R.N., was equally unsuccessful in 1845. Not until 1898 was the existence of the island settled by the German scientific expedition under Prof. Chun in the *Valdivia*, and although the island was photographed, a landing was impossible. Better photographs were taken by the German expedition in the *Meteor* in February 1926, but rough weather made it impossible to land. None of the later expeditions has found more than one island in the neighbourhood, though the Admiralty charts continue to show Thompson Island as reported in 1825. After refitting at South Georgia, the *Norvegia* is proceeding towards Enderby Land, the objective of Sir Ernest Shackleton in the *Quest*, which has never been seen by any expedition since Biscoe discovered it in 1831.

MESSRS. CARL ZEISS, Winsley House, Wells Street, London, W.1, inform us that on Jan. 16, in the presence of the Ministers of Finance and Education, Signore Mussolini signed a contract for the erection of a Zeiss planetarium in Rome. The inauguration will take place on Oct. 29 next, and will be made the occasion of special ceremony. It is intended to erect the planetarium building in a prominent position, and the open space in front of the main station is said to be under consideration for the purpose. The city of Moscow has also recently contracted for a Zeiss planetarium. It is intended to erect the instrument in the building of the former Moscow Circus, situated in the centre of the city. A hemispherical projection surface measuring 26·6 metres in diameter is now being installed, and there will be seating accommodation for about seven hundred spectators. It is expected that the planetarium will be on view in May next.

SIR ERNEST RUTHERFORD, O.M., Pres. R.S., represented the Royal Society at the funeral of Prof. H. A. Lorentz at Haarlem on Thursday, Feb. 9.

IT is announced in *Science* that Prof. T. C. Chamberlin, of the University of Chicago, has been awarded the Penrose Gold Medal of the Geological Society of America.

DR. A. W. HILL, Director of the Royal Botanic Gardens, Kew, who is on a visit, made possible by a grant to Kew from the Empire Marketing Board, to the botanical, agricultural, and forestry institutions of Australia, New Zealand, and Java, has been given the degree of D.Sc. by the University of Adelaide.

AN exchange of greetings by radio telephony between the presidents of the Institution of Electrical Engineers and the American Institute of Electrical Engineers will take place on Thursday, Feb. 16, at 3.30 P.M. The message from America will be received in the Council Room of the Institution, but arrangements are being made for a repetition of the message in the lecture theatre by means of a loud-speaker. Immediately after the exchange of greetings, a kinematograph film, lasting about fifteen minutes, and illustrating the new Anglo-American telephone service, entitled "Voices across the Sea," will be exhibited in the lecture theatre. This will be repeated at 6 P.M.

A new book on the "New Quantum Mechanics" is to be published shortly by the Cambridge University Press. It is the work of Mr. G. Birtwistle and deals with the development of the subject during the past two years. New and hitherto unpublished speculations of Prof. Niels Bohr are promised.

Messrs. Watkins and Doncaster, 36 Strand, W.C.2, announce for early publication "A Revised Handbook of British Lepidoptera," by E. Meyrick. The work is a new form of the author's handbook of 1895, completely revised and remodelled, and largely rewritten, with about 100 additional species, and the classification and nomenclature corrected and brought up-to-date.

Applications are invited for the following appointments, on or before the dates mentioned:—A rural industries assistant, from persons with a knowledge of fur-producing rabbits, under the Somerset Rural Community Council—The General Secretary, 14 Hammet Street, Taunton (Feb. 18). A lecturer in pure and applied chemistry at the Leicester College of Technology—The Registrar, Colleges of Art and Technology, Leicester (Feb. 20). A professor of physics at the University College of Hull—The Secretary, University College, Hull (Feb. 24). A post under the Meteorological Branch, Department of Scientific and Industrial Research, Wellington, New Zealand—The High Commissioner for New Zealand, 415 Strand, W.C.2 (Mar. 6). A senior lecturer in physics at the Huguenot University College, Wellington, South Africa—The Registrar, University College, Wellington, Cape Province, South Africa (Mar. 30). A radiologist electrologist under the Government of Hong Kong—The Private Secretary (Appointments), Colonial Office, Richmond Terrace, Whitehall, S.W.1.

Our Astronomical Column.

Another Test of the Einstein Bending of Light.—It was suggested by Prof. Chas. Lane Poor and others that the observed light bending at the eclipses of 1919, 1922 might be due not to the Einstein effect but to abnormal refraction in the terrestrial atmosphere, produced by the fall of temperature about the time of totality. While it was unlikely that this would act radially from the centre of the sun throughout totality, it was thought advisable to test the suggestion at the Sumatra eclipse of 1926. This was done by Dr. Miller and Dr. Marriott, their method being to obtain the diameter of the moon by photography during totality. The effect if present would affect the moon as well as the stars, while the Einstein effect would only act on the stars.

A recent *Science News Bulletin* issued by Science Service of Washington reports that the measures have now been completed and the moon's diameter has its normal value, thus making the suggestion of the effect being due to terrestrial refraction improbable. A slip in the account in the *Bulletin* should be corrected. It speaks of the Einstein shift as drawing the star-images closer to the sun; actually it pushes them out from it.

Recent Solar Activity.—Although solar activity was considerable during 1927, the rapid rise which characterised the years 1924–26 has received so sudden a check that the average spotted area for 1927 is somewhat less than that of 1926. The appearance of a naked-eye spot has not been reported in Nature since mid-November, but recently there have been several spots, which, although barely large enough for inclusion in this category, have been of interest to observers who regularly watch the sun's disc. In this respect mention should be made of the following spots (the date is given of their passing the sun's central meridian, together with their latitude): (1) Dec. 27, 1927, 12° N.; (2) Jan. 3, 1928, 8° S.; (3) Jan. 22, 15° N.; (4) Jan. 25, 8° N.; (5) Jan. 30, 21° S. On occasions, some of these spots were visible as naked-eye objects to the keenest vision.

In connexion with spot No. 4, Mr. Newbegin, observing at Worthing with his prominence spectroscope, reports that on Jan. 30 he saw a large metallic prominence of the 'rocket' type in the vicinity of this spot near the sun's west limb. The prominence extended to a height of 130″ above the limb, and the displacement of spectral lines indicated considerable motion outwards. The spot itself was not very active, but the *C*-line of hydrogen was reversed faintly, and there were signs of small displacements of the line. It may be added that the 'rocket' type of prominence is one in which streamers shoot out from a common centre which is almost invariably over a sunspot, and that the presence of metallic lines (*e.g.* sodium, iron, magnesium) in the spectrum of the prominence is indication of considerable disturbance. The prominence under observation by Mr. Newbegin showed increasing metallic activity from Jan. 30 until Feb. 1, when it had nearly disappeared around the sun's limb. No unusual terrestrial magnetic disturbance appears to have been recorded when the spot and its attendant prominence was on the disc. Mr. Newbegin adds that on Feb. 2, as many as twenty prominences were seen around the limb.

Bright Meteor on Feb. 3.—Mr. W. F. Denning writes that a fireball was seen from his garden by two observers on Feb. 3 at $7^h\ 56^m$ P.M. It was about twice as brilliant as Venus and pursued a rather long flight in 4 seconds from 99° + 40½° to 27° + 53½°. The radiant point was in the constellation Hydra (which was rising at the time in the east by south) at 148° − 14°, and this position was only just above the horizon at the moment of appearance of the meteor. This radiant in Hydra is in well-defined activity during the months October to February and has been frequently observed. A mean of 15 determinations of the radiant point gives the position at 148° − 11°. It is important to hear of another observation of the bright meteor. Several small meteors were recorded from this shower on Jan. 22 last, and the radiant seems to be one of those long-enduring and fixed positions which appear abundantly distributed over the heavens according to observations during the past half a century.

Research Items.

Bronze Age Urns from South Devon.—What further excavation may prove to be an important discovery relating to the Bronze age is described by Mr. H. G. Dowie in the *Proceedings of the Torquay Natural History Society* for 1926–27. In the course of excavations for a cess-pit at Slapton, South Devon, in July last, two urns were unearthed, and afterwards two stone cists were found. One urn was broken and a majority of the sherds dispersed, but enough have been recovered to show that, apparently, it was undecorated. It was of reddish-brown paste imperfectly fired, with a black core. A fragment of rim suggests a diameter of 9 in. The second urn contained a material of gray colour but no bones. It measures five inches high and is of the same paste as the first. Of the cists, one was in a dilapidated condition. Beneath and around a stone once forming part of the cist were burnt bones, pieces of charcoal, and several human teeth. The second cist was in perfect condition. It lay 25 inches below grass, and consisted of a flat stone for base, five flat stones for uprights, and a cover stone measuring 12 inches by 10 inches. It was almost cylindrical. Burnt bones were found within. The distance between the cists was 4 ft., and the general dispositions of the finds was as if there had been two parallel rows of interments running north-east and south-west. There is no trace of a barrow. The form of the second urn is interesting. Although it approaches the class of early Bronze Age pottery known as 'Food vessel,' in profile its form belongs to the succeeding class of cinerary urn. The decoration of the collar is the alternately shaded triangle. Along the lower curve runs a series of diagonal punctuations. The decorative motive on the collar, though uncommon, is wide spread. The occurrence of an example at Carnac suggests that Slapton may be the terminus of a sea route.

Distributions in North-West America.—Mr. Ronald L. Olson has made a study of the types of adzes, canoes, and houses of the Indian tribes of the north-west coast of America, which is published by the University of Washington as No. 1 of vol. 2 of its Anthropological Series. Mr. Olson's thesis is that, historically, variation is as important as the invention of an entirely new trait. He has therefore taken the three cultural traits mentioned, analysed them in detail, and traced their distribution. Of the adze, the most important tool in wood-working, there are three types in the area, the elbow, the straight, and the D-shaped; their relation is difficult to see. The elbow-shaped type may be an intrusion. The adze, however, is a distinctive north-west trait as opposed to the axe, which is in use over the greater part of America. It may be an Asiatic element, and the occurrence of an elbow form, identical with the American, in Polynesia, suggests an extra American origin. The dug-out canoe is found outside the area over much of California, on the Columbia in Washington, and on all but the upper reaches of the Frazer. On the north it is found only along the coast, excepting for the one instance of the Athabascans of the extreme north-west of British Columbia. It is unknown in Alaska outside Tlingit territory. In north-east Asia it has a wide and sporadic distribution. Both the birch bark and the dug-out canoes of Asia may have spread from America. Their wide distribution in America points to a great antiquity. The rectangular plank house is confined to the north-west coast in the south, but occurs on the upper Frazer and in eastern Washington. It is found in Alaska, while there are comparable types in north-east Asia and in the Amur region, where the resemblance is very close. The general conclusion is that the basic features of the three traits are probably not developments of the north-west coast area, but the restriction of certain qualities to the area is a strong presumption in favour of these being the contribution of tribes in the area.

The Moths of Trinidad.—A catalogue of the Trinidad Lepidoptera Heterocera (Moths) forms No. 3 of the *Memoir of the Department of Agriculture of Trinidad and Tobago* (1927). The authors, Mr. W. J. Kaye and Sir Norman Lamont, Bart., mention that since 550 species of butterflies form the rich fauna of those insects recorded from the island, the number of moths here listed (1016) cannot be considered large. It can be safely assumed that we do not know half of the smaller species of the Pyralidæ, Geometridæ, or Noctuidæ. On the other hand, the Sphingidæ with 54 species, Syntomidæ with 83 species, and Castniidæ with 6 species, are tolerably well represented, and additions thereto are not likely to be numerous. From an economic point of view the number of injurious species is not large, and 28 species of moths pertaining to eight families are listed as habitually or occasionally pests to agriculture or horticulture. The catalogue is evidently very carefully compiled, and should prove useful, not only to entomologists resident in the West Indies, but also to students of geographical distribution elsewhere.

Beetles Injurious to Timber.—A useful pamphlet devoted to this subject has recently been issued as *Bulletin No. 9* of the Forestry Commission (London: H.M. Stationery Office) by Dr. J. W. Munro. Certain Longicorn beetles and pin-hole borers are essentially forest insects, since they attack timber just after it has been felled, abandoning it after it has become dried and seasoned. The powder-post and furniture beetles, on the other hand, attack seasoned timber, the former occurring in timber yards and the latter infesting old furniture, rafters of ancient buildings, etc. A good and well-illustrated account of these several kinds of beetles is given and the types of damage sustained clearly explained, while suggestions are made regarding preventive and remedial measures. The losses occasioned by beetle-attacks to the roofing timbers of Westminster Hall and certain other public buildings are a matter of serious concern to those in charge of the preservation of ancient buildings. There is evidently a good deal of research still to be carried out before a speedy and trustworthy method of treatment can be devised. At present methods require to be periodically applied, even over several years, and no chemical preparation is known which will eradicate beetles from infested timber in a single application.

Indigenous Forest Trees of South Africa.—In a recent paper (*Trans. Roy. Soc., South Africa*, **14**, Part 4) Dr. J. Phillips deals with the ecology and distribution of the large Proteaceous tree *Faurea M'Naughtonii* Phill ('Terblanz'). This tree has the curious distribution of other of the species of the comparatively small area of indigenous forests of South Africa. The species occurs in a single area of about 1000 acres in the Lilyvlei Forest of the Gouna Forest Reserve, Kynsna. It is also recorded from several isolated centres in the Elliotdale, Lusikisiki, and St. John's districts, from Ngorni Forest in Northern Natal, and from Mariep's Kop in the Transvaal. At Gouna there are about 12,000 trees above

1-inch diameter at breast height, and on the 1000 acre portion the absolute frequency of plants under 15 ft. in height and 1-inch diameter is 1·1 per square yard. The percentage frequency of Faurea above 1-inch diameter on the 1000-acre portion is 2·61 per cent. The tree occurs as a dominant in small associations termed the '*Faurea M'Naughtonii*—other spp. associations,' the co-dominants being *Podocarpus Thunbergii* Hook and *Olea laurifolia* Lamk. It is, however, more generally found as a sub-dominant in the extensively developed '*Podocarpus-Olea laurifolia*—other spp. association.' In the Transkei and in Natal the tree is less locally abundant, and is not a dominant in any community. From the forestry point of view it has been established that the tree is moderately light demanding, and is tender in isolation in youth. The dispersal of the fruits (a single-seeded, long villous nut), the author says, is over very short distances, the long hairs being very inefficient aids to flight, whilst water and animals have little influence; the result being the aggregation of regeneration on the crown-influence-zones of the parents. Flowers are produced in considerable abundance, pollination being effected either by a species of Apis or the flowers are self-pollinated. The seeds take from one and a half to three months to germinate, the germinative capacity being ½ to 1 per cent only. It is held that the species is gradually extending its limits at Gouna, where the Forest Department has set aside 200 acres as a scientific reserve.

Iron Ore in South Australia.—The "Mining Review" issued by the Department of Mines of South Australia for the half-year ended June 30, 1927, contains an interesting account of iron mining at Iron Knob, Iron Monarch, Iron Prince, and Iron Baron, which are operated by the Broken Hill Proprietary Company. This Company has constructed a railway line of 3 ft. 6 in. gauge, some 33 miles long, connecting the iron ore deposits with the Port of Whyalla, whence the ore is shipped to the steel works of the Broken Hill Proprietary Company at Waratah near Newcastle, New South Wales. The ore bodies consist mainly of hæmatite with some magnetite, and the quantity of ore proved available for open working is approximately 150 million tons. The ore as shipped contains 65·67 per cent. of iron and 1·69 per cent of silica. A full description is given of the methods of blasting, breaking, and handling the ore, its transportation to the Port and handling at the Port, whilst there is also a brief description of the steel works in New South Wales. It is stated that from the commencement of operations up to Nov. 30, 1926, more than 2¼ million tons of steel ingots have been produced at these works.

Genesis of Kaolinite-bearing Nodules.—In the *Proc. Geol. Assoc.*, pp. 518-547, 1927, Mr. Serge Tomkeieff describes with an admirable wealth of petrographical detail the kaolinite-bearing ironstone-nodules which occur in the Coal Measures near Newcastle-upon-Tyne. The second half of the paper discusses the various problems that arise in connexion with the genesis of the deposit, and as this part of the investigation is based on sound geology and a clear appreciation of physical and colloidal chemistry, the result is a contribution to petrogenesis of wide and unusual interest. An outline of the processes involved is as follows: (*a*) Deposition of fine laminated mud with an original pore space of nearly 90 per cent.; (*b*) segregation of colloidal hydrated iron carbonate and hydrated alumino-silicates in the form of nodules under the protective action of humic acids, the nodules being thus of the penecontemporaneous class; (*c*) gradual crystallisation of the colloform nodules from the outside inwards, with subsequent cracking of the interior due to syneresis; (*d*) gradual compression of the shale; (*e*) infiltration of solutions into the crack-spaces and deposition of kaolinite and calcite. It is suggested that the kaolinite represents materials that were in colloidal solution, and that, as they lost water, they formed a colloidal precipitate,

$$2H_4SiO_4 + 2H_3AlO_3 - 5H_2O = H_4Al_2Si_2O_9,$$

which gradually passed into a finely crystalline aggregate. The interesting observation is recorded that a bleached Cheviot granite from under a thick covering of peat contained no trace of kaolinite.

Divisions of the Alps.—At the congress of Italian geographers, held at Genoa in 1924, a commission was nominated with the task of forming a scheme for the nomenclature of the region and districts of the Alps. This work was much needed in order to give precision in writings on the Alps, for there has been hitherto considerable divergence in the application of various names. A map in the *Geographical Journal* for January gives the findings of the Italian commission and is accompanied by a short critical article by Mr. D. W. Freshfield. The principle adopted by the commission was that geological, climatic, linguistic and political boundaries must be ignored if the nomenclature is to have real practical value. Only orographical considerations have been kept in mind and, where possible, rivers and passes rather than mountain crests have been utilised as boundaries. For details, reference must be made to the map, but it may be noted that with a few exceptions the districts as now defined correspond more or less closely with those adopted by W. A. C. Coolidge in the "Encyclopædia Britannica."

The Standard of Length.—When Arago took part sixty years ago in the conferences which led to the construction of the standard metre of the newly founded Bureau international des Poids et Mesures, he expressed himself most enthusiastically on the advantages of a unit of length defined in terms of the wave-length of a line of the spectrum of a particular element, for example, the red line of cadmium, and since his day others have expressed the same opinion with equal enthusiasm. But the work of spectroscopists during the last twenty or thirty years has shown that there are many circumstances and conditions which affect the wave-length of a line of an element, by small amounts it is true, but each year almost has added to the known conditions which must be satisfied if the standard line is to be obtained. It is mainly on this account that M. A. Pérard, of the Bureau, after an examination of the facts, comes to the conclusion in a paper in the *Travaux et Mémoires* of the Bureau, that for the present the old platinum standard must serve as the definition of the unit of length, nor can quartz serve as a substitute for platinum.

Passive Metals.—An X-ray examination of finely divided iron, nickel, and chromium, conducted by F. Krüger and E. Nahring at Greifswald, has shown conclusively that films of oxide thicker than 10^{-7} cm. are not present on the surface of a passive metal. The diffraction pattern of an inert sample is identical with that of a chemically reactive specimen, and exhibits not only no extra lines where those of the oxides would be expected, but also shows those of the ordinary metal in their usual positions, proving that the pre-existing lattice has not undergone appreciable distortion. The plate which accompanies their paper in the *Annalen der Physik* (No. 23) shows distinctly the pattern of nickel oxide (NiO) superposed on that of nickel, when in order to test the sensitivity of the method, a mixture of the two substances was taken which contained only 2 per cent. of the former.

Use of the Geiger Electrical Counter.—The conditions under which this instrument can be used to enumerate β-rays accurately have been studied by Dr. N. Riehl in Fraulein Meitner's laboratory in Berlin, and are described, together with some allied work on radium *D* and radium *E*, in the *Zeitschrift fur Physik* of Jan. 13. An important point overlooked by previous investigators is that in order to record with certainty a fast β-particle, producing less than about ten pairs of ions per cm. at atmospheric pressure, the density of gas in the ordinary type of counter must be increased. Dr. Riehl considers that neglect of this factor, and the application of an unduly large correction for reflection at the source, make previous estimates of the number of β-particles from radium *E* too small, and gives 1·2 as a new minimum value; in other words, about one in six of the particles constituting the continuous spectrum with speeds up to about 0·94 that of light are of secondary origin. The radiation from radium *D*, on the contrary, could only be partially recorded when the stopping power of the celluloid window of the counter was reduced to 0·45 mm. air-equivalent, and apparently the bulk of the primary β-rays from this element have velocities less than one-fifth that of light.

Miners' Lamps.—The flame of a modern safety lamp is quite visible through the glass cylinder which now forms the lower part of the lamp, and the candle power of the lamp varies from 0·8 to 1·2. The problem of increasing this candle power has been under consideration by the Safety in Mines Research Board for some time, and Paper No. 40 just issued by the Board (London: H.M. Stationery Office) gives an account of the work of Prof. R. V. Wheeler and Mr. D. W. Woodhead in this direction. They find that by using a blend of petroleum spirit with paraffin and mineral colza, an increase of 35 to 40 per cent. in the candle power is obtained. By increasing the height of the wire gauze chimney, using a wider mesh, a thinner wick with its top concave upwards and by surrounding the upper part of the flame by a short length of glass tubing open at top and bottom, the candle power can be raised to 2·75. It is to be hoped that these possibilities will become widely known and that lamp manufacturers will quickly place these improved lamps on the market.

The Photographic Detection of Falsified Documents.—Prof. Carlo Bonacini contributes an article on this subject to the *Rivista Fotografica Italiana*, a translation of which appears in the *British Journal of Photography* for Jan. 20. He finds that a photograph made by means of the infra-red shows chiefly superficial details, while the ultra-violet brings out detail more in the body of the document. This method demonstrated in one case that underneath the visible number was another number, invisible: that it had been effaced by chemical means, but had evidently left a clear trace in the fibres of the paper. He also confirms the work of Colson, that a document written in an easily oxidisable ink (as iron gallate), if left for a sufficient time in contact with a gelatino-bromide plate, will cause desensitisation where the ink is, so that if the plate is developed after a brief exposure to light, the writing will be shown transparent on a grey background. Prof. Bonacini finds that by this means one can reproduce an inscription that has been bleached by chemical means. In an example, the visible inscription being written with an ink made with a dye, this method revealed only the original writing that has been bleached and was quite invisible. He enumerates certain details in connexion with these methods that need further investigation.

High Temperature Equilibria.—An ingenious method for the investigation of high temperature equilibria has been developed by C. H. Prescott, Jr., and W. B. Hincke, and some new results are recorded in the November issue of the *Journal of the American Chemical Society*. The furnace employed consisted of a thin graphite tube about one-third of a centimetre in diameter, supported on tungsten rods and mounted in a bulb in a thermostat. The materials were placed in the tube and the temperature raised by passing a heavy current through the graphite. An optical pyrometer was used to determine the temperature. The equilibrium between thorium oxide, thorium carbide, and carbon monoxide was investigated between 2000° and 2500° K. at pressures varying from 2 cm. to 2 atms. The thorium carbide, ThC_2, produced was a yellow crystalline substance which hydrolysed in a short time to a buff-coloured powder even over phosphorus pentoxide. Its melting-point is in the neighbourhood of 2773° K. The aluminium oxide and carbon system was similarly examined. The data obtained were utilised to calculate the free-energy and heat-content changes attending the reactions:

$$ThO_2 + 4C = ThC_2 + 2CO\,;$$
$$2Al_2O_3 + 9C = Al_4C_3 + 6CO.$$

Circuit Breaking at High Pressures.—The new problems which electrical engineers have to consider are mainly connected with high pressures and methods of breaking circuits supplying large amounts of electric power. The use of high pressure is made necessary by the greater distances the power has to be transmitted. Problems connected with underground cables up to pressures of 100 kilovolts and overhead wires up to 380 kilovolts have been practically solved, but engineers are still chary about adopting them. The solutions for high pressures cannot be obtained by a simple proportional increase of the dimensions of apparatus and cables. Entirely new electro-technical problems are involved which need exhaustive and prolonged study in the laboratory before the engineer can safely proceed to carry out high-pressure schemes involving the control of huge amounts of power. The question of the rupturing capacity of large oil-break circuit breakers can only be solved experimentally. Not even a roughly approximate theory has yet been given to indicate the effects that would be produced by increasing the number of breaks in a circuit or increasing the speed at which the contact pieces separate. This is a rich field for research and offers excellent prospects of technical developments. In *A.E.G. Progress* for October, Dr. Rengier discusses the relative advantages of multi-break interruption and explosion chambers in circuit breakers for use in polyphase systems. The arc which occurs on the separation of the contacts converts the oil in its neighbourhood into gas and vapour. As the oil gas mixes with the metallic vapour, the metallic vapour arc alters into a gas arc. The gas, which is under considerable pressure, offers increased resistance to the maintenance of the arc. On the other hand, the high gas temperature diminishes the resistance. The author shows that by fitting the oil circuit breaker with 'explosion chambers,' increased security can be obtained as the energy liberated in the apparatus is diminished.

Geology in Great Britain.

THE *Summary of Progress of the Geological Survey*[1] for the year 1926 is more than usually interesting, because it contains not only the annual report of the Geological Survey Board and that of the Director, but also a series of appendices in which are presented the results of some of the more important investigations made during the year under review.

Revision of the six-inch maps is being actively carried on in most of the British coalfields. Sixty-four maps were published last year, together with a number of memoirs, some of which are noticed briefly below. The appendices include accounts of the Silurian rocks of Wenlock; the Carboniferous Limestones of Cumberland and the Isle of Man; the Barnsley Seam; the Pliocene of the Surrey Downs; the Ochil Fault; and, perhaps most noteworthy of all, a long technical paper on "The Use of the Torsion Balance in the Investigation of Geological Structure in South-West Persia." This very able report, by W. E. P. McLintock and J. Phemister, provides a welcome account of the method of investigating deep-seated structures by means of the Eotvos balance, and also of some of the actual results achieved by the Anglo-Persian Oil Company. The latter is to be congratulated for its generosity in consenting to the publication of a report which the Board rightly felt would be of outstanding interest to geologists generally.

A memoir on the Wrexham District[2] describes the area represented on Sheet 121, an area that lies mainly within the county of Denbigh and includes the densely populated belt of the Denbighshire coalfield. The geological sequence described ranges from the Bala formation to the top of the Millstone Grit, which, in this neighbourhood, is roughly equivalent to the upper part of the Carboniferous Limestone. Special attention is devoted to the tectonic features of the district, and to the chief fossil localities.

The Stafford memoir[3] describes the area of Sheet 139, an agricultural district of red Keuper Marl and lighter Bunter and Glacial soils that lies between the Potteries and the South Staffordshire coalfield. The formations present include small patches of Carboniferous Limestone and Middle Coal Measures, but the Triassic rocks are dominant. Petrologists will be specially interested in the account of the Dyke of Butterton and Swynnerton, a dyke which is remarkable in that it cuts Triassic rocks. Various mineral products are described, including salt and brine; and the chief sources of water supply are discussed.

The area of the Rossendale Anticline[4] stretches west from the Pennines into Lancashire and embraces the high ground between the towns of Blackburn, Burnley, Todmorton, Rochdale, Bury, and Bolton. The structure and stratigraphy of the local Carboniferous rocks are described in more detail and greater precision than have hitherto been possible, palæontological methods of classification and correlation having been successfully adopted. The zonal forms of the difficult Millstone Grit series recently worked out by Mr. W. S. Bisat have been critically checked in this area. Other chapters are devoted to the glacial deposits and to various mineral products, of which coal is, of course, the chief.

The country around Ipswich[5] is of extraordinary geological interest, a fact which is partly due to and partly proved by the active research which it has stimulated in recent years. It typifies the late Cretaceous, Tertiary, and Pleistocene geology of East Anglia, and, thanks to the labours of Mr. J. Reid Moir, it has yielded a more complete series of worked flints than any other district in Britain. Dr. G. Slater has found in the glacial formations structures of which the investigation has led to most valuable and far-reaching results. Prof. P. G. H. Boswell has made many authoritative contributions to the geology of the district. His life-long interest in the area, and the inevitable linking of his name with the history of its investigation, make it particularly appropriate that his services should have been enlisted by the Survey to prepare the official memoir. The hand-coloured map is now replaced by a new colour-printed edition of Sheet 207, the price of which is two shillings.

All the above publications are published by H.M. Stationery Office, London, and the Ordnance Survey Office, Southampton.

A New Reflex Micrograph.

THE increasing use of the microscope for routine tests, and as an instrument of control in the factory, has resulted in directing the attention of makers and users to the production of microscopes of the projection type. The use of such instruments obviates the eyestrain that arises from prolonged and continuous observation at the eyepiece of an ordinary microscope. A new type of instrument—the Ramsden reflex micrograph—which has been designed by Lieut.-Col. J. V. Ramsden, and is marketed by Messrs. Micrographs, Whiston, Ford, Shrewsbury, and by Messrs. James Swift and Son, 81 Tottenham Court Road, London, W.1, constitutes a combined projection microscope and photomicrographic outfit embodying several novel features. In its mechanical design and construction, the instrument entirely departs from the traditional form of microscope stand.

The microscope tube carrying the objective and the ocular, with the objective pointing upwards, is fitted into a long bush in the box-like metal body of the instrument. Vertical guide bars mounted at one side of the body carry a lamp-house which contains a source of light for use when transparent objects are being examined. By means of a mirror mounted on the vertical guides, the rays of light from the lamp are reflected through the microscope on to a metallic mirror, from which they are reflected on to a screen so placed as to be convenient to the eye and close to all the controls for the operation of the instrument. The screen is shaded by a hood into which a mounted magnifying lens may be inserted when it is desired to examine the aerial image or to obtain more critical focussing.

When a photographic record of the image is required, the screen is withdrawn and a photographic plate inserted in its place. A recess in the metal of the body permits of the insertion of a ruled glass plate just below the screen or the photographic plate, by means of which objects may be measured at a glance or records of the measurement may be obtained on each photograph. The title, or a description of the object under examination, may also be obtained on the plate at the same time as the object is photographed. A card on which the title has been written is placed on a slide which is inserted through an opening in the side of the body. The card is illuminated by a lamp within the body and its image projected by a lens on to the photographic plate.

The rack and pinion movement of the usual type of microscope has been replaced by a spiral screw of 1 mm. pitch cut on a cylindrical steel rod. This rod passes through an adjustable hollow pillar which is mounted vertically at one side of the body. The stage and the sub-stage are clamped to this pillar and can be moved up or down by turning the divided head at the top of the rod. Fine adjustment is effected by the rotation of an eccentrically mounted steel disc operating a lever, the short arm of which raises or lowers the pillar carrying the stage.

For the observation of opaque objects the instrument is provided with two horizontal guide bars mounted on the top of the body. These carry a second lamp house and also a condensing system. Vertical illumination is obtained by means of reflectors of the Beck universal type which can be slipped into a mirror holder mounted on the microscope tube in such a manner as to be capable of being moved backwards and forwards, and of being tilted in any direction. Entire control of the illumination is thus obtained.

The instrument described can be used for metallurgical, biological, or petrological work. Simpler types have been designed for use in routine work, where a universal instrument is not required. Geometric bearings have been adopted for all sliding parts so as to secure ease of movement and accuracy of adjustment. The instrument is built throughout on the lines of a precision machine tool. The design obviates the introduction of any delicate part, and the construction is such that the instrument may, if necessary, be put into the hands of an unskilled operator without fear of damage.

A New Bottom-Sampler for Oceanographical Research.

PROF. MARTIN KNUDSEN has published (*Meddelelser fra Kommissionen for Havundersøgelser*, Serie: Fiskeri, Bind 8, Nr. 3, 1927) an account of a new instrument which he has designed for obtaining samples of the sea bottom, together with the animals living therein. It is specially designed for use on hard bottoms, such as compact sand, where it has been realised that the instrument in most general use, the Petersen grab, is seriously lacking in penetrative power. The new sampler is filled by means of a pump which surmounts it, and the catch is retained by an ingenious 'tipping' device. The pump is operated from on board, being driven by a drum which is made to revolve by the same cable that serves for lowering and hauling the machine. An excellent feature of the sampler is that, when operating properly, it provides a sample which is stratified as *in situ*.

An accompanying paper (Nr. 4 of the same publication) by Dr. A. C. Johansen gives an account of the preliminary trials of Prof. Knudsen's sampler and furnishes a quantitative comparison of the samples obtained by this method with samples collected at the same time and under the same conditions by means of the Petersen grab. The trials show that the new instrument samples the sea-floor to a depth of 12·0-25·0 cm., as compared with a penetration of but 0·5-3·0 cm. by the Petersen grab. The area sampled is 0·1 square metre, and tables are given comparing the catches with those by two Petersen grabs sampling 0·1 square metre and 0·2 square metre respectively.

The quantitative results of these comparison tests are very striking. The average amount of bottom material per unit area taken by the Knudsen sampler on sandy bottom was found to be more than twenty times that taken by the smaller Petersen grab and more than ten times that taken by the larger. The average weight of animals captured per unit area was about five times that taken by the smaller grab and about four times that by the larger. The alcohol weight of the animals taken in one comparison off Fanø was for the Knudsen sampler about thirty times that obtained with the smaller grab and more than twenty times that with the larger, whilst the bulk of the species taken were totally unrepresented in the grab hauls, showing conclusively the vital importance of penetrating far enough into the bottom to obtain the burrowing species.

There is, therefore, ample evidence of the success of Prof. Knudsen's bottom sampler and of its importance and value for quantitative investigation of the sea bottom. The sampler is necessarily somewhat complicated and as described would probably be difficult to operate in other than calm and shallow waters. The principles embodied in it, however—utilisation of pressure to fill the sampler and the 'tipping' device for retaining the catch—will be of great service to all concerned in the elaboration of methods for investigating marine bottom populations.

Science and Primary Production.

IN his presidential address to the Australasian Association for the Advancement of Science, at Hobart, on Jan. 16, Mr. R. H. Cambage referred to the great need for the further application of science to primary production. This embraces such fundamental utilities as the production of grain, fruit, butter, wool, and meat, and it is a matter for satisfaction that the Commonwealth and State Governments, as well as private bodies, are showing increased appreciation of the value of science to these problems. A few years ago a thorough knowledge of dairy bacteriology and its application to the production of butter, resulted in increasing the output of first grade butter in New South Wales from 48 to 96 per cent.

When referring to wheat Mr. Cambage said: "It is difficult to find anything among the primary products of Australia which owes more to science than wheat production. This is a matter of national concern, and it is most comforting to know that the great pioneering work carried out by William James Farrer is not only being continued at Departmental experiment farms and Universities, but with most progressive results. New and better drought and rust-resisting varieties of wheat and other grain are being produced, and experiments are being made for the purpose of breeding rust and flag-smut-resisting plants which will also have other good characters."

Reference was made to the action of the pastoralists in arranging for the Australian Pastoral Research Trust to receive a contribution at the rate of two shillings a bale of the 1927 wool-clip, with the hope of raising £200,000 for scientific research in connexion with the industry. This action Mr. Cambage regards as a most definite advance in Australia in the recognition of the benefits of science.

The Federal Government recently invited five leading pastoralists to act as a committee to inquire into the conditions of the pastoral industry in Australia, and advise on the best methods of conserving the national wealth represented by the industry. This provides further evidence that the authorities concerned are quite alive to the necessity of abandoning the old happy-go-lucky methods of trusting to chance in regard to seasons, but rather look for the introduction of some reasonable scheme of insurance that may have for its object the avoidance of excessive losses rather than the making of enormous profits.

Mr. Cambage concluded the first portion of his address by saying that it is the desire of the Australasian Association for the Advancement of Science, which includes New Zealand, to inspire and stimulate a science sense in the public mind, and this, he believes, can best be done by demonstrating how the principles of pure science may be applied successfully to familiar economic problems.

University and Educational Intelligence.

Birmingham.—The annual meeting of the Court of Governors is to be held on Feb. 23. The Vice-Chancellor, in his report to be presented to the Court, gives the usual statistics, which show that the number of students for the year 1926–27 was the lowest since the post-War boom. The number for the current session, however, shows an increase.

The sixth annual report of the Joint Standing Committee for Research is a record of the work accomplished and in progress during the session, and indicates a healthy activity in all faculties. Among the donations recorded is one from "a Firm in Birmingham" for research in the recent history of industry in Birmingham and the Midlands. This research is being carried out by the Faculty of Commerce. The anonymous charitable trust which has hitherto subscribed £600 per annum to meet the stipend of the reader in geography, has now decided to hand over to the University sufficient capital to produce the necessary income annually, thus putting the readership on a permanent basis.

Cambridge.—Dr. D. R. Hartree, St. John's College, and Mr. T. M. Harris, Christ's College, have been elected to fellowships at Christ's College. Mr. L. R. Jones, Emmanuel College, has been elected to the Nita King Scholarship for research in the etiology, pathology, and prevention of fevers.

The Council of the Senate has presented to the University a report proposing to open to women candidates from Girton and Newnham College, on the same terms as to men, practically all the scholarships, studentships, and prizes at present confined to members of the University.

London.—Mr. M. E. Delafield has been appointed, as from a date to be determined later, to the University chair of chemistry as applied to hygiene tenable at the London School of Hygiene and Tropical Medicine. He was educated at Merchant Taylors' School and at Jesus College, Cambridge (Scholar and Exhibitioner). From 1910 until 1916 he was engaged in medical practice, and from 1920 until 1925 he was Deputy Medical Officer of Health for the Metropolitan Borough of Stoke Newington. Since 1925 he had been head of the Department of Public Health and Hygiene at University College. He has acted for some time as one of the sectional editors of the *Bulletin of Hygiene*.

The following doctorates have been conferred: *D.Sc. in Biochemistry* on Mr. H. G. Reeves (King's College) for a thesis entitled "Researches on Intermediate Carbohydrate Metabolism—the Preparation, Properties, and Physiological Significance of dl-Glyceric Aldehyde"; *D.Sc. in Zoology* on Mr. B. K. Das (Imperial College (Royal College of Science)), for a thesis entitled "The Biology and Post-larval Development of some Air-breathing Fishes of India"; *D.Sc. in Engineering* on Mr. H. W. Swift, for a thesis entitled "Orifice Flow," together with seven subsidiary contributions.

Dr. E. L. Kennaway has been awarded the William Julius Mickle Fellowship for 1928 in respect of the work he has carried out on cancer research during the past five years. The Fellowship this year is of the value of about £275.

Oxford.—In a Convocation held on Jan. 31, the annual reports of the Committees for Anthropology and Forestry were presented to the House, and leave of absence was granted to the Savilian professor of geometry, Prof. G. H. Hardy, in order to enable him to exchange work for the next two winter terms with Prof. O. Veblen, of Princeton University. On the same day a vote of thanks was accorded to Sir John Findlay, Bart., for a gift to the Lewis Evans Collection of Scientific Instruments of a valuable silver microscope made by George Adams for King George III.

Alternative decrees for dealing with the Bodleian Library will be proposed in Congregation on Tuesday, May 8 next.

Dr. Gustav Hertz, professor of experimental physics in the University of Halle, has been appointed to succeed Prof. Kurlbaum as professor of physics at the Technische Hochschule, Berlin.

Five Fellowships, each of the annual value of £200 and tenable for two years, are being offered to graduates of the University of Wales. Applications should be sent to the Registrar, University Registry, Cathays Park, Cardiff, not later than June 1.

Applications are invited by the London School of Hygiene and Tropical Medicine for the Wandsworth scholarship for research in tropical medicine, value £370 per annum, plus travelling and subsistence allowance for work overseas. The latest date for the receipt of applications by the Secretary, School of Hygiene and Tropical Medicine, Malet Street, W.C.1, is April 29.

Leplay House Educational Tours Association is organising three tours for the coming Easter vacation: to the Balearic Islands, under the leadership of Mr. G. Morris; to Normandy with Mr. W. Keesey; to Montpellier with Prof. P. Geddes. Particulars can be obtained from Miss Margaret Tatton, Leplay House, 65 Belgrave Road, Westminster, S.W.1.

The annual examinations will be held at Faraday House Electrical Engineering College on April 3–5 for a Faraday Scholarship of fifty guineas per annum, tenable for two years in College and one year in manufacturing works, and for a Maxwell Scholarship of fifty guineas per annum, tenable for one year in College and one year in works. Exhibitions may also be awarded. Particulars can be obtained from the Registrar, 62-70 Southampton Row, London, W.C.1.

Calendar of Customs and Festivals.

February 14.

ST. VALENTINE'S DAY.—St. Valentine, priest and martyr at Rome under Claudius II., the patron saint of lovers and more particularly of girls, for no reason which is very apparent from his legend. Traditionally he is characterised by the attribute of chastity. The most noteworthy event in his life is the restoration of her sight to the blind daughter of the Roman official Asterius, in whose house he was confined, which led to the conversion of the whole household. They were afterwards martyred with him. The obscure and indeed almost incongruous coupling of the saint with lovers has been explained as a substitution by the church of his festival for one observed at about this time by the Romans, more specifically said to be a feast of Juno Februata, in which boys and girls pledged themselves to one another. It is doubtful how far this explanation has the warrant of antiquity. St. Francis de Sales is said to have forbidden the custom of valentines, that is of giving boys in writing the names of girls to be waited on and admired by them, and substituted billets with the names of certain saints to be honoured and imitated. Another tradition bases the association on the fact that the saint's martyrdom took place at the time of the great Roman festival of purification, on Feb. 15—the Lupercalia. The legendary connexion with Roman observances associated with the spirit world is also indicated in the belief, noted in the old Romish calendar quoted by Brand, that ghosts walk on the night of Feb. 14.

In popular custom, the traditional observances of the day go back to at least medieval times. The custom of choosing valentines obtained in the fifteenth century, as is shown by one of the Paston letters, and there are references to it in the poems of Charles of Orleans, written while he was captive in England, and in Lydgate, Chaucer, and Gower, and frequently in poets of later days. In the poets, as in rustic tradition, the day is also associated with the pairing of birds. Similar customs were noted in France, and, though scarcely relevant, mention may be made of a belief embodied in a quatrain in a French almanack for 1672 on the virtues of blood-letting on St. Valentine's Day.

The pledging of lovers on St. Valentine's Day might be by chance, the first member of the opposite sex seen on the morning of Feb. 14 being the Valentine, or it might be a matter of deliberate choice. The most widely prevalent early form of the custom, however, was by lot, each member of a party—first the boys, then the girls—drawing a slip of paper on which the name of a member of the opposite sex was written. The difficulty of the double lot was overcome by preference or by the lot drawn by the boy prevailing. In its less sophisticated form the lot of the valentine was regarded as a good omen of the pair becoming man and wife. The choice of a valentine, whether deliberate or fortuitous, entailed some obligation on the man to confer gifts on his valentine—an obligation which in Scotland was reciprocal, and perhaps originally was so universally. The gifts were sometimes of considerable value, such as the jewel of the value of £800 given to Miss Stewart by James, Duke of York, at the Court of Charles II. Pepys, who mentions the drawing of valentines on several occasions, also dwells on the expense to which he was put by the presents involved. The custom of sending presents to the valentine survived well into the nineteenth century. Pepys also records the drawing of mottoes for the valentine in addition. This is one of the earliest references to the literary form of valentines, which later came to be sent anonymously, and from being poetical degenerated into the comic or even the obscene, before it practically died out, at any rate as a generally observed custom, in the latter part of the nineteenth century.

Young people greeting their parents and others with "Good morrow, valentine," the first thing in the morning, before themselves addressed, were said to 'catch' their valentine. A present followed. In Norfolk the 'catch' had to be effected before sunrise; otherwise the would-be catcher was 'sun-burned.'

Other customs associated with St. Valentine's Day are of some significance. Its connexion with the pairing of lovers made it a time especially suitable for divination in connexion with love affairs. Various methods were practised, such as a triple drawing of lots, or by the number of objects seen through a keyhole, or by casting various names on paper wrapped in clay pellets into water. A ritual not dissimilar from that enjoined on the eve of St. Agnes, including the eating of an egg which had been stuffed with salt, was observed in order to obtain a vision of the future consort. Girls were told to pray, with their legs crossed, to St. Valentine on this day for good luck. Another method of divination practised on the eve of St. Valentine was to scatter hempseed on the way home, after a vigil in the church porch, while reciting a charm. This evoked the image of the future mate raking up the hempseed into a winding-sheet. Here, as often, divination is close to the spell.

In some parts of the country the children roamed from house to house singing a valentine song for coppers. In Herefordshire they decorated themselves with wreaths and lovers' knots thrown to them from the house first visited; but one of their number, the youngest and a boy, was decked out more gaily than the rest. This brings the valentine into touch with the central figure of spring festival processions.

A Derbyshire custom was 'sweeping the girls.' If any girl were not kissed or visited by her sweetheart early in the morning, it was because she was 'dusty.' She was then swept with a broom and well kissed by the young men in the house or from the neighbourhood.

Finally, a curious custom from the west of England may be noted. Three single young men went out together at daylight with a clap net to catch an owl and two sparrows in a neighbouring barn. If they were successful, and could bring the birds to the house before the women had risen, they were entitled to three pots of purl in honour of St. Valentine.

The obvious difficulty in attempting to associate St. Valentine in any way with the popular customs and beliefs observed on his day and the character of the observances themselves, notwithstanding their sophistication in many respects, point not only to a pagan but also to a very remote origin. It is obviously a pairing custom; but scarcely to be related, as an anticipation, to the strict observance of the ecclesiastical fast of Lent, when marriage or a formal betrothal could not be solemnised; nor does it appear cognate to the carnival, though it may have a common forerunner with that period of license. The fortuitous mating, which was sometimes thought to portend, and often did lead to, a wedding, the divination, and especially the triple lot, the interchange of gifts, which probably at one stage represented a forfeit for non-compliance with custom, suggest a derivation from a ceremonial period of unrestricted and universally imposed sexual intercourse such as is found among primitive peoples at stated seasons as part of a religious ritual for the promotion of fertility in the animal and vegetable world.

Societies and Academies.

London.

Royal Society, Feb. 2.—**A. V. Hill**: The air-resistance to a runner. The air-resistance to a model of a running man has been measured in a wind-channel, and found to be 0·45 $\rho v^2 A$, where ρ is density of air, v relative velocity, and A projected area of model in direction of motion. This is 0·00170 $v^2 A$ lb. weight (v feet per sec., A sq. ft.). The projected area of a runner is approximately = square of his height × 0·15. For a runner on a still day the air never provides more than 5 per cent. of total resistance, the remainder being in his own muscles and limbs. A following wind of 10 miles an hour will increase speed about 3 per cent.; a similar head-wind will diminish speed about 5 per cent. The correction for air-resistance is too small to affect materially the equations previously found for the acceleration of a runner at the beginning of a race.

S. M. Manton: On the embryology of a mysid crustacean, *Hemimysis Lamornae*. Germ layers and the general rudiment are differentiated externally on the germinal disc. Gastrulation takes place by immigration from a blastoporal area. The mesoderm forms in three ways. A row of eight mesodermal teloblasts give rise to the trunk mesoderm; a pair of head bands of mesoderm supply the naupliar segments and in front of these a pair of pre-antennulary somites is formed. Cœlomic cavities appear in all except antennulary, mandibular, and maxillulary segments. The yolk cells or vitellophags represent true endoderm. They form secondary yolk pyramids and give rise directly to mid-gut epithelium. The liver is formed from posterior parts of head mesoderm bands. The endoskeletal system is ectodermal, as is also much of the musculature. The antennal gland is mesodermal, except for the short ectodermal exit tube.

G. M. Findlay: Immunological and serological studies on the viruses of fowl-pox and vaccinia. Three strains of fowl-pox virus have been studied: two are pathogenic for the fowl only; one is pathogenic for fowl and pigeon. All attempts to render these three strains pathogenic for rabbits, rats, calves, and ducks have failed. One attack of fowl-pox produces immunity. In the fowl any one of the three strains completely immunises against the others, but in the pigeon previous treatment with the strains pathogenic for fowl produces only partial immunity against the strain pathogenic for pigeon and fowl. Vaccinia virus passaged in the fowl does not become converted into fowl-pox virus, and remains pathogenic for rabbit and rat. Vaccinia virus and fowl-pox virus do not show any cross-immunity in the hen. Anti-vaccinia serum from hen has no viricidal action on virus of fowl-pox, nor has anti-fowl-pox serum viricidal action on the virus of vaccinia. While fowl-pox virus easily passes through a Berkefeld filter, vaccinia virus, even after repeated passage in the hen, is still largely held back. No evidence was obtained showing any close relation between virus of vaccinia and the three strains of fowl-pox virus investigated.

E. Sprawson and **F. W. Bury**: The chemical evidences of the organic content of human enamel. Previous analyses of enamel differ widely, from an unmeasurable trace of organic matter to 16·56 per cent., most of the work being on enamels of lower animals. An attempt has been made, after eliminating carbonates, to estimate quantitatively the residue of carbon and total nitrogen present. If present as some form of protein, these should show the same ratio to each other as in protein, and from the amount of either found, the percentage of protein in enamel can be calculated. Specimens of human enamel were obtained from deciduous young permanent and adult permanent teeth. New tests, qualitative and quantitative, of particular delicacy and accuracy, showed both carbon and nitrogen to be present—nitrogen to an extent indicating a maximum organic content of 0·15 per cent., carbon indicating up to 0·21 per cent.

R. J. Ludford: Studies in the microchemistry of the cell (1). When sections of suitably fixed material are submitted to mild hydrolysis, treated with fuchsin-sulphurous acid, and thoroughly washed in sulphurous acid, the nucleo-proteids of cells are stained an intense purple or violet colour. Chromatin alone is stained in the cells. In sections through a tar tumour and surrounding skin, no difference was apparent in the amount of chromatin of normal and malignant cells. It was not found possible to correlate any relationship between amount of chromatin in tumour-cell nucleus and rate of growth of tumour. Large nuclei often contain approximately the same amount of chromatin as do small, but the giant nuclei which occur in some tumours, and are apparently formed by fusion of smaller nuclei, contain large masses of chromatin.

R. J. Ludford: Cytological studies on the viruses of fowl-pox and vaccinia. Virus bodies produced by vaccinia on the skin of the chick are exactly the same as those of fowl-pox, in structure, in origin, and in the development. Vaccinia virus produces in the epidermal cells of the rat's cornea inclusions closely resembling those of the chick, but differing fundamentally in the absence of covering osmophil substance, characteristic of virus bodies of the chick. Vaccinia virus can be transmitted from rat's cornea to the skin of the chick, where it results in the formation of characteristic virus bodies. Chick virus does *not* bring about the same result in epidermal cells of rat's cornea. One strain of fowl-pox was found to produce in epidermal cells of the pigeon the same type of virus bodies as in the chick, but was without action on epidermal cells of the rat's cornea.

Mineralogical Society, Jan. 10.—**L. J. Spencer**: Potarite, a new mineral discovered by the late Sir John Harrison in British Guiana. Small nuggets and grains of a brittle white metal have been found very sparingly by diamond-washers in the neighbourhoop of the Kaieteur Falls on the Potaro River. This mineral, previously erroneously described as 'allopalladium,' was proved by Harrison to be a compound of palladium and mercury, PdHg, with a density (15·0-16·1) considerably higher than that of either of the component metals. There is a crystalline structure which on the surface of one nugget is shown as indistinct cubic octahedra. The original 'allopalladium' from the Harz Mts., supposed to be a hexagonal modification of palladium, could not be procured for a re-examination; it is probably the ordinary cubic palladium.—**H. V. Ellsworth**: A simple and accurate constant-volume pyknometer for specific gravity determination. The pyknometer of 10 c.c. capacity is made of silica-glass, thus possessing several advantages over one made of ordinary glass. The stopper is perforated by a capillary and is continued into a graduated side-tube, which dips under water while the apparatus is cooling. The volume of the contained water to the graduations on the side-tube can be readily and accurately determined to 0·0002 c.c.—**W. Campbell Smith**: The optical orientation of labradorite from County Down (Ireland) determined by the Fedorov method. The labradorite from basaltic dikes at St. John's Point, Ardglass, Co. Down, of which the chemical composition and refractive indices were published in 1912, has been studied by the Fedorov method and the optical orientation determined.

Geological Society, Jan. 11.—**G. M. Lees**: The geology of south-eastern Arabia. South-eastern Arabia consists of two separate tectonic and stratigraphic provinces: (1) A foreland where, as at Dhofar, ancient gneiss is overlain by a 'Nubian' type of desert-sandstone. (2) An orogenetic zone of typical Alpine character. The relation of Oman to the Zagros arc is discussed. The characteristic zone with red and green radiolarites and shales and basic igneous rocks occurs again in Persia, and forms great tracts of country south-west of Kerman. Here also Upper Cretaceous rocks are strongly unconformable. One great branch of the Cretaceous orogenetic zone of Central Persia must, therefore, have passed southwards into Oman. The Upper Cretaceous-Tertiary geosyncline broke down across the older strike, and pursued an independent direction parallel to the present Persian Gulf-Mekran coast. The late Pliocene movements also followed this trend, the influence of the older tectonics only being shown in the marked swing of the strike between Bandar Abbas and Jashk. Such a complete independence of these two phases of Alpine movement is unique. The Oman orogenetic zone may be followed through Masirah Island to Ras Madhraka, where it passes southwards into the Arabian Sea. The Kuria Muria Islands belong already to the foreland. A further movement, though of much less intensity, took place in Oman in post-Miocene time. South of Sur these folds strike north-west and south-east, and appear to pass out to sea at Ras al Hadd, independent of, and across, the older structures. Perhaps these folds form a continuous loop with the Kirthar Range of Sind, but no connexion can have existed between the latter and the Cretaceous orogen of Oman. The Triassic, Lower, and Upper Cretaceous fossils are described.

Paris.

Academy of Sciences, Jan. 3.—**V. Smirnoff**: Orthogonal polynomials with one complex variable.—**Florin Vasilesco**: Some points in the theory of harmonic functions.—**Georges Valiron**: A general theorem on meromorph functions of positive order.—**L. Escande**: The technique of reduced models of barrages with overflow weir. Four models of the weir were made on a reduced scale, 1/19·5, 1/100, 1/150, and 1/300 of the actual weir, and the actual flow determined for each as a function of the head of water. The four curves shown do not coincide exactly. The yield shown by a model is less than the actual flow on full scale, the extrapolation error being on the side of safety. The divergence increases as the model is made smaller.—**L. Hirschauer** and **A. Talon**: The formula for the ultra-rapid propulsion of extra-light vehicles on rails.—**René Darbord**: The reactive power.—**M Geloso** and **Mlle. L. S. Lévy**: Researches on selective adsorption.—**A. Wahl** and **J. Rolland**: The chlorobenzoylacetic esters.—**Mme. Ramart-Lucas** and **F. Salmon-Legagneur**: Intramolecular transposition by photochemical action. Isobutyl bromide after exposure to the radiation of a mercury arc lamp for four hours is partially converted (4 per cent.) into tertiary butyl bromide: after forty-eight hours' exposure, 13·5 per cent. is converted. The reaction is considered from the point of view of the hypothesis of semivalence.—**M. Gignoux**: A layer of Triassic vegetation near Saint-Jean-de Maurienne (Savoie).—**Albert Morel** and **Léon Velluz**: Contribution to the study of the biochemical synthesis of the glycerides. The reversibility of the diastatic action of the cytoplasm of castor-oil seed.—**Constant Mathis**: The identity of the spirochaete of the shrew mouse and the human spirochaete of Dakar. All the experimental work described tends to prove the identity of these two diseases. It only remains to find the agent of transmission from the animal to man.

Rome.

Royal National Academy of the Lincei, Nov. 6.—**G. Giorgi**: Doppler phenomenon of acceleration.—**S. Minetti**: The necessary and sufficient conditions for an entire function to be of a certain genus and of a certain order.—**S. Cherubino**: The notion of parity and the real character of real Abelian varieties.—**G. Vitali**: A covariant derivation in generalised absolute calculus (2).—**M. Pastori**: Bernouilli's surfaces.—**G. Gherardelli**: An observation on the Jacobian series of a linear series.—**B. Caldonazzo**: Certain properties of permanent liquid motions, the vortices of which are normal to the velocity.—**Lodovico Stranoo**: The conditions of validity of some developments of functional operators.—**C. Cannata**: Contribution to the ballistic theory of variable stars.—**G. Tiercy**: The problem of the colour index in astronomy.—**G. Piccardi**: Relationships between the ionisation potentials of homologous elements. In the case of helium and the alkaline-earth metals, the relationship between the atomic number and ΔV, the difference between the ionisation potential of an element and that of the corresponding fundamental element—that is, the element having a single electron in the external orbit on which the element concerned has its peripheral electrons—is expressed by a continuous curve (1). In the zinc-cadmium-mercury group, passage from an element with one electron to one with two electrons (of the same orbit s) is accompanied by an increase in the ionisation potential which is a well-defined function of the atomic number. For other groups of elements, the laws connecting ionisation potential with increase in the number of electrons in the same orbit are obtained by multiplying the ordinates of curve (1) by 1 for the quadrivalent elements (C group), 2 for quinquevalent and sexivalent elements (N and O groups), 3 for the halogens, and 5 for the rare gases.—**A. Ferrari** and **C. G. Fontana**: Structure of silver chlorate. The lattice of this salt consists of a tetragonal cell of dimensions $a = 8{\cdot}48$ A. and $c = 7{\cdot}91$ A., containing eight molecules.—**L. Settimj**: Chemical composition of certain food species. The results of analyses are given for the following common Italian foods: tinned meats of various ages, fresh lean beef, cheese, stockfish, lean bacon, and dried mushrooms (*Boletus edulis*).—**C. Antoniani**: The influence of superphosphate on the reaction of the soil. When applied to neutral or almost neutral bare soils free from lime, superphosphate effects a gradual but slight acidification; the opposite results recorded by other investigators are influenced by the presence of a growing crop or by other factors.—**U. Panichi**: Independent elements of symmetry of the first and second species.—**E. Benedetti**: Certain modifications in the course of alcoholic fermentation due to the action of the oscillating electromagnetic field on the yeast (2). The alteration produced in the course of alcoholic fermentation by subjection of the yeast to an oscillating electromagnetic field for 35-40 minutes varies with the frequency of the oscillation. With a low frequency (272·7 kilocycles), the fermentation is accelerated, the extent of the acceleration increasing for some hours and then remaining virtually constant. A similar, but less marked effect is observed with a frequency of 400 or 500, whilst for the value 1200 the fermentation is retarded.—**T. Terni**: Histological modifications in the thymus of birds resulting from castration and from old age.—**C. Gorini**: Investigations on disgenesic milk.—**V. Puntoni**: Elimination of the virus of rabies by the digestive tract. The results of experiments on dogs indicate that the old theory of the salivary elimination of the virus of rabies should be replaced by a more comprehensive theory, according to which the whole of the mucus and almost all the glands of the digestive tube must be regarded as surfaces for the elimination of this virus.—**A. Galamini**: The action of ethyl alcohol on the renal secretion. When ingested in the proportion of 0·5-0·75 c.c. per kilo of body weight, alcohol of 95 per cent. concentration, diluted to double its volume with water, invariably exerts a diuretic action, varying in degree with different individuals. The quantity of alcohol eliminated with the urine in successive periods follows the quantities of alcohol present in the blood at an interval of about 30 minutes, and reaches a higher level.

VIENNA.

Academy of Sciences, Nov. 10.—**L. Moser** and **J. Singer**: Determination and separation of rare metals from other metals (10). Three new gravimetric determinations of beryllium and separations based on them. By gallo-tannic acid in the presence of ammonium acetate, beryllium can be separated from iron, aluminium, chromium, titanium, zirconium, thorium, tungsten, and vanadium. A dense beryllium hydroxide can be precipitated by the hydrolysis of the beryllium ion with ammonium nitrite in the presence of methyl alcohol. A third method involves the formation of $Be_2P_2O_7$, similar to the magnesium method. A crystalline precipitate of the ammonium salt is obtained in the presence of weak acids (acetic or citric).—**R. Schwinner**: The structure of the mountains east of the River Lieser in Carinthia.—**L. Waldmann**: Geological structure of the Moldau-Danubian primitive rocks on the map sheet Gmünd-Litschau; also report on the geological survey of the Moravian primitive rocks in Lower Austria.—**A. Marchet**: Report on researches on the eruptive rocks of Gleichenberg in East Styria. Chemical analyses of trachite and andesite have been made.

Nov. 17.—**O. Halpern**: Quantum statistics.—**M. Holly**: Fishes from Kamerun—a new species of silurid.—**L. Kolbl**: Alpine tectonics of the Altvater hills.—**E. Chwalla**: The stability problem of a circular arc in a plane.—**W. J. Müller** and **K. Konopicky**: The theory of passivity: a theory of polarisation as to anodic covering and passivity of metals. A mathematical equation is given, and the cases of copper, iron, nickel, and chromium considered. The potential of the metal does not alter, but the apparent alteration of potential is to be traced to a change of resistance due to extension of a surface layer.—**A. Muller** and **A. Sauerwald**: New synthesis and purification of hexamethylenimine.—**E. Bersa**: Actinobiological researches. The action of Rontgen rays on the nuclear division of the root tips of *Zea mais*. There is a transitory depression of the frequency of cell division, but vegetative growth is not markedly altered. Also the influence of Rontgen rays on the respiration of the root-tips of *Vicia faba*.—**A. Zinke**, **K. Funk**, and **H. Ipavic**: Researches on perylene and its derivatives (16).—**A. Ginzberger** and **H. Zerny**: Expedition to the Lower Amazon, Pernambuco, and Para.

Nov. 24.—**A. Muller** and **E. Rolz**: A new and simple preparation of 1, 7-dioxy-*n*-heptane (heptamethyleneglycol) and 1, 7-dibrom-*n*-heptane.—**D. B. Anderson**: The structure of collenchyma cell-wall deduced from micro-chemical investigations. The cell-wall collenchyma of *Solanum lycopersicum* is neither chemically nor physically homogeneous, but consists of lamellæ which are alternately pectin and cellulose. Normal collenchyma between crossed Nicols appears to be doubly refracting. After treatment with ammonio-cuprous oxide, cellulose is removed, and the cell-walls are isotropic. The lamellæ can be separated after treatment with potassium iodide and sulphuric acid.—**A. Winkler**: New results of inquiries into the inner Alpine tertiary.

WASHINGTON, D.C.

National Academy of Science (*Proc.*, Vol. 13, No. 11, November).—**Arthur A. Noyes** and **Arnold O. Beckman**: A periodic table of the structure of atoms and its relation to ion formation and valence. A chart has been prepared from spectroscopic data showing the number, the quantum states and the energies of removal of the electrons from the outer shells of the atoms and ions of the first twenty-six elements. Atomic numbers are the abscissæ, and the square roots of the energies absorbed in the removal of the electrons from the atoms, in terms of the energy absorbed in removing the electrons from the hydrogen atom, are the ordinates. The chart indicates the mode of ion formation and is suggestive as regards valencies.—**Oliver R. Wulf**: The magnetic behaviour of ozone. An armature of pyrex glass (20 cm. long × 8 mm. diameter) was suspended from a balance so that the lower end came between the poles of a large electromagnet. The force exerted on the armature was measured when the armature was surrounded by air, oxygen, and an ozone-oxygen mixture. Experimental conditions produced effects comparable with the deviations to be measured, so the pyrex armature was replaced by a tube of soda glass containing oxygen at atmospheric pressure. The results showed that ozone is diamagnetic and its volume susceptibility is a small fraction of that of oxygen.—**Morgan Ward**: General arithmetic.—**W. L. Ayres**: On the structure of a plane continuous curve.—**E. T. Bell**: On the arithmetic of Abelian functions.—**G. A. Miller**: Groups whose operators are of the form s^pt^q.—**Joseph Kaplan**: The continuous spectrum of hydrogen. Horton and Davies observed that hydrogen at pressures less than 1 mm. of mercury, when excited by electrons of less than 15 volts velocity, becomes suffused with a blue glow with no atomic or molecular lines. This continuous spectrum appears to arise when the molecule, in the first electronic state and possessing more than 0·5 volt of vibrational energy, splits into two atoms.—**Arthur Edward Ruark** and **Harold C. Urey**: The impulse moment of the light quantum. It is suggested that the light quantum has a property corresponding to the spin of the electron. Various consequences of such a property are worked out and experiments likely to afford evidence of its existence are suggested.—**H. Bateman**: The symmetry of the stress-vector obtained by Schroedinger's rule.—**H. B. Vincent**: Some extensions of theory and measurement of shot-effect in periodic circuits.

Official Publications Received.

Diary of Societies.

SATURDAY, February 11

Mining Institute of Scotland (at Heriot Watt College, Edinburgh), at 3.—D C Gemmell: Supporting Underground Roadways with Steel Arches.—Papers open for discussion:—An Improved Face Conveyer, A. V. Reis.—The Transport of Injured Persons Underground, D Davidson.

Royal Institution of Great Britain, at 3.—H. C. Colles: Musical London from the Restoration to Handel (1660–1759) (I)

Fédération Britannique des Comités de l'Alliance Française (at London Day Training College), at 3 15.—M Moureu: Marcelin Berthelot (Lecture).

Hull Association of Engineers (at Technical College, Hull), at 7 15.—W A E. Woodman. The Lubrication of Prime Movers.

MONDAY, February 13.

Charity Organisation Society (at Denison House, 296 Vauxhall Bridge Road), at 3 30.—Sir William H. Hamer, Dr. E. Graham Little, and Dr. H. Nockolds: Discussion on the Voluntary Hospitals and the Public Authorities Chairman: Lord Dawson of Penn.

Royal Geographical Society (at Lowther Lodge), at 5.—Dr. C. Crossland: The Island of Tahiti.

Royal College of Surgeons of England, at 5.—Dr. A. Abrahams: The Physiology of Violent Exercise in Relation to the Possibility of Strain.

British Psychological Society (Education Section) (at London Day Training College), at 6.—Miss Mary Chadwick The Child's Early Discrimination between Sound and Speech.

Institution of Automobile Engineers (Birmingham Centre) (at Queen's Hotel, Birmingham), at 7.—C. R. F Engelbach. Works Re-organisation to Increase Production

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—H. B Poynder: Some Practical Considerations in the Design of Automatic Equipments for Heavy Traction Sub-stations

Ceramic Society (at North Staffordshire Technical College, Stoke-on-Trent), at 7 30.—F. West: Practical Experience of Firing Refractory Materials with Oil.—C. E Jackson and A Heath: Florida Clay in China Bodies.

Institute of Metals (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—D. R. Tullis. Further Notes on Aluminium Alloys

Royal Society of Arts, at 8.—H. Gough Fatigue Phenomena, with Special Reference to Single Crystals (Cantor Lecture) (I)

Institute of Chemistry (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry (Edinburgh and East of Scotland Section)) (at North British Station Hotel, Edinburgh), at 8.—Dr. Kermack and Dr C P Stewart Report upon the Preliminary Investigation into Personal Errors in Chemical Determinations

Institution of Electrical Engineers (Western Centre) (at Bristol).—A. H. Law and J. P. Chittenden Higher Steam Pressures and their Application to the Steam Turbine.

TUESDAY, February 14

Royal Society of Medicine (Psychiatry Section) (at Maudsley Hospital, Denmark Hill), at 4.—Clinical Meeting.

Royal Institution of Great Britain, at 5 15.—Prof. A. P. Newton: The Dependent Empire and the British Commonwealth of Nations, 1870–1926

Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.—C. Dalley. Causes of Fires in the Petroleum Industry and Methods of Prevention.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—T. Thorne Baker: Television and Electric Image Transmission

Institute of British Foundrymen (Lancashire Branch, Burnley Section) (at Municipal College, Burnley), at 7 15.—Mr. Goodyer Semi-Steel

Institution of Automobile Engineers (Coventry Centre) (at Broadgate Café, Coventry), at 7 30.—C. R. F. Engelbach: Works Reorganisation to Increase Production.

Institution of Electrical Engineers (Scottish Centre) (at Royal Technical College, Glasgow), at 7.30.—D S Munro Modern Electric Wiring, particularly as applied to Small Houses.

Quekett Microscopical Club (Annual General Meeting), at 7.30.—Presidential Address.

Hull Chemical and Engineering Society (at Photographic Society, Grey Street, Hull), at 7 45.—J. B. Upton: Westinghouse Brakes

Pharmaceutical Society of Great Britain, at 8.—C. E. Corfield and P. A W. Self The Correlation of Analytical Data and Accuracy in Dispensing

Royal Anthropological Institute, at 8.30.—Prof F G. Parsons: The Increasing Size of the Skull

WEDNESDAY, February 15.

Society of Glass Technology (in Applied Science Department, Sheffield University), at 2 30.—W. Singleton: The Analysis of Opal Glasses.—J. T Howarth and Prof. W. E. S Turner The Study of a Fundamental Reaction in Glass Making.—David Starkie and Prof W. E S. Turner: Note on the Ultra-Violet Ray Transmission of Colourless Bottle Glass

Institution of Heating and Ventilating Engineers (at Holborn Restaurant), at 2 30.—S. B Horrocks Presidential Address.—Discussion on Report of the Fan Standardisation Committee.

Royal College of Surgeons of England, at 5.—A. Fleming: Lysozyme, a Bacteriolytic Ferment normally present in Tissues and Secretions

Institution of Civil Engineers (Students' Meeting), at 6 30.—W T. Shaddock: New Training Bank at South Haven, Poole Harbour.

Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7.—E C. McKinnon: Storage Batteries in Relation to Modern Supply to Electric Lighting and Power.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (Newcastle-upon-Tyne), at 7 15.—L C. Burrill: Floating Docks.

Merseyside Aquarium Society (at 1 Falkland Road, Egremont), at 7.30.—G. A Dunlop: The Science of the Sea.

Royal Meteorological Society, at 7 30.—Dr. J Glasspoole: The Distribution over the British Isles of the Average Number of Days with Rain during Each Month of the Year.—Memoirs to be discussed.—The Single-layer Problem in the Atmosphere and the Height-integral of Pressure, by L. F. Richardson and R. E Munday.—The Variance of Upper Wind and the Accumulation of Mass, by L. F. Richardson, D Proctor, and R. C. Smith

Royal Microscopical Society, at 7 30.—D. J. Scourfield: A New Type of Aquarium Microscope.—Prof. J. T. Wilson: Description of a Convenient Table for Microscopy.

Royal Institute of British Architects, at 8.—Sir E. Owen Williams: Bridges.

Royal Society of Arts, at 8.—Capt. Sir Beachcroft Towse: The Education of the Blind.

Royal Society of Medicine (Social Evening), at 9.15.—Col. W. P. MacArthur: Some Medical References in Pepys.

Institution of Mechanical Engineers (Liverpool Branch) (jointly with Liverpool Engineering Society).—Prof. C. J. Hawkes: The Marine Oil-Engine (Thomas Lowe Gray Lecture).

Institution of Mechanical Engineers (Sheffield Branch).—E. G. Herbert: Cutting Temperatures: Their Effect on Tools and on Materials subjected to Work.

Institute of Chemistry (Manchester and District Section).—Prof. J. R. Partington: Some Manchester Scientists.

THURSDAY, February 16.

Eugenics Society (at Rembrandt Hotel, Brompton Road).—2.30 to 6.—Exhibitions. Demonstrations: Miss O. C. Lodge, Health and Education; Eldon Moore, Agricultural Shows.—At 7.15.—C. J. Bond: The Distribution of Natural Capacity in the Population and the Need for National Stocktaking (Galton Lecture).

Royal Society, at 4.30.—Prof. A. Fowler and E. W. H. Selwyn: The Arc Spectrum of Carbon.—R. H. Fowler: The Chemical Constant of Hydrogen Vapour and the Failure of Nernst's Heat Theorem.—A. H. Wilson: (*a*) The Ionised Hydrogen Molecule; (*b*) A Generalised Spheroidal Wave Equation.—C. H. Walters and S. Barratt: The Alkaline Earth Halide Spectra and their Origin.—*To be read in title only*:—Prof. T. R. Merton: On a New Effect in the Electric Discharge.—S. W. Watson and M. C. Henderson: The Heating Effect of Thorium and Radium Products.—C. C. Farr and D. B. Macleod: Some Physical Properties of Gas-freed Sulphur.—Prof. H. F. Baker: Note on the Paper 'Commutative Ordinary Differential Operators' by J. L. Burchnall and T. W. Chaundy.—L. S. Ornstein, W. Kapuscinski, and J. G. Eymers: Intensity Measurements in the Secondary Spectrum of Hydrogen.—P. A. M. Dirac: The Quantum Theory of the Electron (II.).

Linnean Society of London, at 5.—E. Heron-Allen: On the Further Researches of J. J. Lister upon the Reproductive Processes of *Polystomella crispa* L.—M. A. C. Hinton: False Killer-Whales in the Dornoch Firth.—Mrs. L. Hunter: Alcyonaria of the Abrolhos Islands.

London Mathematical Society (at Royal Astronomical Society), at 5.—W. N. Bailey: Transformations of Generalised Hypergeometric Series.—P. Hall: Note on Soluble Groups.—Prof. L. J. Mordell: (*a*) The Magnitude of the Derivate of a Function; (*b*) A Summability Convergence Theorem.—G. Temple: The Computation of Characteristic Numbers and Characteristic Functions.—E. C. Titchmarsh: On Conjugate Functions.—F. J. W. Whipple: On Series allied to the Hypergeometric Series with Argument −1.

Royal Institution of Great Britain, at 5.15.—Sir William Bragg: From Faraday's Note Books (III.). The Colours of Gold.

Child-Study Society (at Royal Sanitary Institute), at 6.—Sir Humphry Rolleston, Bart.: Child Guidance.

Institution of Electrical Engineers, at 6.—A Cinematograph Film entitled Voices Across the Sea, illustrating the New Anglo-American Telephone Service.—D. S. Munro: Modern Electric Wiring, particularly as applied to Small Houses.—A. J. Milne and R. H. Rawll: The Domestic Applications of Electricity.

Royal Aeronautical Society (at Royal Society of Arts), at 6.30.—Dr. G. P. Douglas: Experiments on Model Air-Screws at High Tip Speeds.

Society of Chemical Industry (Birmingham and Midland Section) (at Birmingham University), at 7.—Papers by Dr. W. J. Hickinbottom and Dr. E. L. Hirst.

Chemical Society, at 8.—R. S. Morrell and S. Marks: Studies in China Wood Oil. Part II. The Oxidation of b Elaeostearic Glyceride.—W. M. Madgin, J. B. Peel, and Prof. H. V. A. Briscoe: Cryoscopic Evidence of Compound-formation in Mixtures of Organic Liquids.—Prof. H. V. A. Briscoe and J. B. Peel: The Preparation and Properties of Selenophene, Tetrabromoselenophene and Tetrachloroselenophene.

Lancaster Astronomical and Scientific Association (at Storey Institute, Lancaster), at 8.—Dr. T. Green: Colour in Nature.

Royal Society of Tropical Medicine and Hygiene (at 11 Chandos Street, W.), at 8.15.—Dr. A. R. Paterson: The Provision of Medical and Sanitary Services among Rural Populations in Tropical Africa.

Institution of Mechanical Engineers (Birmingham Branch).

Institution of Mechanical Engineers (Manchester Branch).—Major W. Gregson: Waste Heat Recovery.

FRIDAY, February 17.

Glasgow University Alchemists' Club (jointly with Andersonian Chemical Society) (at Glasgow University), at 3.30.—Debate.

Royal College of Surgeons of England, at 5.—Dr. I. C. Mann: The Regional Differentiation of the Vertebrate Retina.

Society of Chemical Industry (Liverpool Section) (jointly with Manchester and Fuel Sections) (at Liverpool University), at 6.—H. H. Thomas: An Examination of the Influence of Various Factors on the Products of Carbonisation of Coal.

Institution of Mechanical Engineers (Annual General Meeting), at 6.—Major W. Gregson: Waste Heat Recovery.

Institute of Marine Engineers, at 6.30.—Annual Meeting.

Royal Photographic Society of Great Britain (Informal Meeting of Pictorial Group), at 7.—J. D. Johnston: Changing Ideals in Pictorial Photography.

Junior Institution of Engineers (Informal Meeting), at 7.30.—St. John Plevins: Oil Production.

Royal Institution of Great Britain, at 9.—Rev. Dr. E. M. Walker: The University: Its Ideals and its Problems.

Society of Dyers and Colourists (London Section).—M. C. Lamb: The Dyeing of Gloving and Clothing Leathers.

Society of Dyers and Colourists (Manchester Section, jointly with Junior Section).—F. Scholefield: The Standardisation of Fastness of Coloured Textiles.

Electroplaters' and Depositors' Technical Society (at Sheffield).—Conference on The Electrodeposition of Silver:—Dr. H. Be Saniger: Recent Work on Electrodeposition of Silver.—A. H. Nicol: Silver Plating.

SATURDAY, February 18.

North of England Institute of Mining and Mechanical Engineers (at Newcastle-upon-Tyne), at 2.30.

Royal Institution of Great Britain, at 3.—H. C. Colles: Music in London from the Restoration to Handel (1660–1759) (III.).

Physiological Society (in Department of Physiology, University, Manchester).

PUBLIC LECTURES.

SATURDAY, February 11.

Horniman Museum (Forest Hill), at 3.30.—M. A. Phillips: In the Haunts of the Sea-birds.

MONDAY, February 13.

Gresham College, at 6.—G. P. Bailey: Modern Science and Daily Life. The Inter-relationship of the Elements.

East Anglian Institute of Agriculture (Chelmsford), at 7.—H. P. Weller: Factors affecting Farm Profits.

University of Leeds, at 8.—Dr. Ll. Wynn Jones: Recent Advances in Experimental Psychology: Doctrines and Methods established during the last twenty-five years.

TUESDAY, February 14.

Gresham College, at 6.—W. H. Wagstaff: Geometry. (Succeeding Lectures on Feb. 15, 16, and 17.)

British Institute of Philosophical Studies (at Royal Society of Arts), at 8.15.—Prof. J. Laird: The Possibility of Rationalism in Ethics.

WEDNESDAY, February 15.

Royal Institute of Public Health, at 4.30.—Dr. W. M. Feldman: Medico-Legal Aspects of Jewish Life.

THURSDAY, February 16.

University of Leeds, at 8.—A. N. Shimmin: Economics in Everyday Life: The Process of Earning a Living.

FRIDAY, February 17.

King's College, at 5.30.—K. Kyriakides: Social Life in Cyprus in the Middle Ages.

SATURDAY, February 18.

Horniman Museum (Forest Hill), at 3.30.—Miss M. A. Murray: Amulets and Magical Figures of the Ancient Egyptians.

CELEBRATION.

February 14 and 16.

Bicentenary of John Hunter (at Royal College of Surgeons of England).

February 14, at 4.—Sir Holburt Waring: Hunterian Oration.

February 6, at 5.—G. C. Peachey: London Homes of the Hunters (Thomas Vicary Lecture).

CONFERENCE.

February 21 to 24.

Carbonisation Conference (in Birmingham and Midland Institute and Queen's College, Birmingham).

Tuesday, February 21 (in Birmingham and Midland Institute).

At 10.30 A.M.—

W. J. A. Butterfield: The General Scope of the Gas Industry.

T. Hardie: Some Phases of Modern Practice in Gas Manufacture.

T. Hardie: Presidential Address to the Southern Association of Gas Engineers and Managers.

M. Barash and T. C. Finlayson: Continuous Vertical Retorts.

N. J. Bowater: Vertical Intermittent Chamber Ovens for Gas Manufacture.

R. H. Ruthven: Intermittent Vertical Chambers.

Wednesday, February 22 (in Birmingham and Midland Institute).

At 10 A.M.—

C. P. Finn and B. Ray: The General Scope of the Coke Oven Industry.

G. J. Greenfield and G. H. Harrison: Modern Coke Oven Practice.

H. C. Evans: Coke Research and the Steel Industry.

Thursday, February 23 (in Birmingham and Midland Institute).

At 2.30—

T. F. E. Rhead: Steaming in Vertical Retorts.

A. T. Green: Gas Works Refractories.

Dr. A. Parker: Gas Works Effluents.

Friday, February 24 (In Queen's College).

At 10 A.M.—

Sir Arthur Duckham: The Handling, Preparation, and Utilisation of Gas Works Coke.

J. Roberts: Blending in the Gas and Coke Oven Industries.

At 2.15—

F. S. Sinnatt: A General Review of Low Temperature Carbonisation.

Science and Leadership.

SOME instruction in science is now provided at most of the secondary schools in Great Britain. Such instruction, in the case of the boys' schools, usually takes the form of an introduction to chemistry and physics, while in girls' schools botany and chemistry are frequently the only branches of science taught. For various reasons, which have so often been the subject of reference in these columns that they need not be repeated now, those pupils who show any aptitude for science are mostly led for the last two years at school to tread the path of specialisation on their journey to the universities. They arrive at the universities embryo chemists, physicists, or botanists, where they are hatched out as full-fledged specialists destined to act as guides to others along the same narrow paths, or to apply their specialised knowledge to industry or in one or other of the public services. Only the comparatively few forsake the paths of specialisation and find scope in leadership and control for the exercise of the particular qualities of mind engendered by the study of science.

The demand for early specialisation in science is as vicious in principle and as harmful in its effects as the demand for any form of early vocational training for the children of the less favoured classes of the community. The revolt against the old-fashioned classical education was successful because the teaching of the classics had become so specialised that the main object of the study was obscured. It encouraged the worst forms of pedantry: it was de-humanised. There is abundant evidence that the teaching of science is suffering from the same disease. The spirit of science, the systematic observation of facts, the conception of hypotheses, to be discarded if they cannot be verified over a complete range of observations, or enunciated as universal if they stand such test, the constant challenge to established precedents and authority, is apt to be obscured by a mass of technical trivialities which passes for scholarship. The influence of scientific discovery upon man's outlook and activities is too often ignored by teachers of science. They incline to look at their several subjects from the inside, and thus not only lose sight of the unity of purpose of the whole range of scientific study, but also fail to appreciate the important impacts of this study upon our common stock of ideas.

At the recent meeting of the Science Masters' Association, Prof. W. A. Bone opened a discussion on "Industrial Openings in Scientific Technology."

He reminded his audience that the profound change in conditions during the past twenty-five years had increased the need in every branch of industry for scientific control and direction, not only in the actual processes of manufacture but also over the whole range of activities precedent and subsequent to the production of finished goods. The nation that could think farthest ahead and adjust its system accordingly was the nation that would deserve success. It behoved us, therefore, as a nation, to ensure that our industrial leaders were men trained in scientific method and in modern scientific thought, who could foresee change and prepare for it. At least seven years' training was necessary, three years studying fundamental science subjects before graduation, to be followed by four years of specialisation.

Within the limits of the subject under discussion, it was obviously difficult for Prof. Bone to deal with the more general applications of the principles he enunciated for industry. This is a pity. As we have already suggested, the teaching of science in schools and most universities is vitiated by over-specialisation, with the resulting tendency to produce experts in the narrowest sense of the term. What is most needed at the present time is an appeal to the science masters in our schools to break with a bad tradition, and by broadening the basis of instruction in science, particularly by the inclusion of biological studies, to extend the mental horizon of their pupils. University teachers will then be the better enabled to equip science students for the responsibilities attaching to the most coveted positions, not only in industry and finance but also in the spheres of higher administration in State and local government services, the various colonial services, and even the judiciary.

Most of us will subscribe to the view that no person can be considered well educated who lacks the equipment to discern the principal forces which are operating to mould our environment. Undoubtedly some knowledge of science and some training in scientific method are essential for such discernment. For the control and direction of affairs, more than this general training is and should be required. It is doubtful whether anyone who lacks the capacity for independent and perspicacious inquiry should be entrusted with the cares of leadership. The field of research is sufficiently extensive to provide abundant opportunity for testing such capacity. It behoves us to follow some such procedure in choosing our leaders, rather than continue to leave it to chance circumstance to produce them.

To prevent misunderstanding, let us state definitely that it is not contended that the creative research workers of any country should be hampered by administrative duties. Such research workers are sufficiently rare to be given every form of encouragement to extend the bounds of knowledge. Their requirements are met by giving them all the facilities they need for their work, the greatest amount of freedom from external control, and freedom from pecuniary worries. It does not follow that we agree with the oft-repeated assertion that such men are unfit for administrative control. The success of Newton as Master of the Royal Mint is by no means the exception which proves the accepted rule. Our view is that no country can afford the luxury of diverting them from the pursuit of new knowledge and its dissemination. Their gift of vision is the world's greatest asset: their function is leadership in a supreme degree. Happy the community that is intellectually equipped to appreciate their genius and possesses the will to follow them.

It is the other types of research workers for whom we consider more varied and abundant opportunities should be given for the exercise of their talents. They may be concerned with the critical examination of discoveries being made in a particular field of knowledge with the view of their application, or they may be engaged on what is embraced by the term 'development work.' But because of the existing prejudice in Great Britain against the so-called experts, they are rarely placed in a position to accept full responsibility for the execution of their ideas. Possibly this prejudice is more ingrained in the hierarchy of the Civil Service than elsewhere. Cases are on record where administrative officers have come to decisions on technical questions without even consulting the technical advisers of the department. It is repeatedly asserted in administrative circles that a man with intensive knowledge of a particular subject is incapable of unbiased judgment on any matter within its scope upon which there may be difference of opinion. Consequently, when a Royal Commission was appointed to inquire into the state of the coal industry, its members included no scientific authority. It is true that the Commission was assisted by a scientific assessor, but no actual member of the commission was competent to examine the scientific experts who gave evidence before it. We are assuming, of course, that finance and economics cannot be regarded as exact sciences.

Obviously there are historical reasons for the prejudice against the expert in the State service.

The prejudice, however, should be attributed to the expert's virtues rather than to his vices. The State machine is activated by bias—the bias of one or other of the political parties. The scientific expert who is faithful to his training must deal with facts objectively and not subjectively. Like the lawyer, it is his function to weigh evidence, but unlike the lawyer it is not his function to select only those facts which support his preconceived hypotheses. If the weight of evidence is against his hypotheses, he must find others. It is only natural that the politician, and the administrative head of a department who has to serve him, often to the extent of writing a memorandum demolishing all the arguments in a memorandum on the same subject which he had prepared a few months before under a different regime, should display a preference for the legalistically minded adviser. The scientific expert cannot be expected to be so accommodating.

Ethical considerations apart, let us assume that the present machinery of government is such that it demands for the smooth working of certain of its parts a type of administrative officer whose function is to serve as a buffer to lessen the shock of impact of impartial judgments on the political heads of the State machine. It does not follow that every part of the machine must be subject to the same control. The State has made itself progressively responsible for providing certain services, the efficient administration of which is entirely dependent upon the way our available resources of technical skill and scientific knowledge are utilised. It is farcical to pretend that they can best be utilised by those who are ignorant of those resources, any more than it is safe to assume that the ignorant will seek impartial advice or be unbiased in their judgments. We suggest that the present machinery of government is in need of overhaul. An attempt should be made to differentiate clearly between those departments whose principal functions are political, and those whose activities are governed solely by financial considerations. It is not denied that successful administration depends upon a knowledge of the administrative system, but we fail to understand why this knowledge cannot be acquired by those who have had the advantage of the broad training we suggest in the methods and principles of science.

As we have already said, many desirable changes in the teaching of science would be effected if the choice of career of science students were not so limited. Their predetermination to specialisation is bad for them and worse for the country which has built up the tradition. In the continental countries there is no such tradition. Men trained in science occupy the highest positions in the State and industry. This may account for the rapidity with which the scientific discoveries of our countrymen are applied to industry in Germany, and possibly afford an explanation for the slow development of the tropical possessions of Great Britain in comparison with the rapid development of those of the Dutch.

It is high time a survey were made of the positions for which candidates, in addition to that ill-defined quality—personality—should possess a sound knowledge of science. We can think of none where this knowledge would not be an advantage. It would lend reality to finance, to the direction of industry, to the administrative services, and even to politics. It would increase our respect for the law if the judges in the special courts dealing with technical matters were themselves able to differentiate between what is and what is not science. It would be worth while trying the experiment of appointing scientifically trained men as governors of our non-self-governing dependencies, instead of distinguished soldiers, sailors, or politicians. But it is unlikely that any such survey will be made until there are far more members of the House of Commons who have a knowledge of and abiding interest in science and faith in its methods. It would hasten the day if more teachers of science appreciated the social implications of their studies and led their students to realise that modern statecraft must be based upon a comprehensive study of the sciences.

The Clinician and Chemotherapy.

Principles and Practice of Chemotherapy: with Special Reference to the Specific and General Treatment of Syphilis. By Prof. John A. Kolmer. Pp. xvi + 1106. (Philadelphia and London: W. B. Saunders Co., 1926.) 55*s.* net.

HITHERTO most of the literature of chemotherapy has been written by chemists, or at least by investigators with a bias towards chemistry. It is wont to consist of descriptions, in series, of complex organic compounds contributed by the chemist, to which his biological colleagues, the pharmacologist and the parasitologist, add 'toxicities' and 'curative doses,' the latter being the minimum quantity of each substance found necessary to cure some particular infection induced experimentally in one of the lower animals. If the ratio between the two factors is favourable for any member of the series, that substance becomes a possible candidate for clinical trials, so that the clinician has the last word in deciding whether the work of his chemical and biological colleagues is to have the chance of becoming a practical success. Such practical successes are rare, and are far more limited in their application than is generally believed, even by that restricted public which concerns itself with matters of scientific interest.

Fortunately, the contribution which chemotherapy makes to the welfare of humanity is not measured solely by these occasional therapeutical bull's-eyes, but by the steady growth of systematised knowledge of the mode of action of drugs, which its study inevitably ensures, and this accretion of knowledge is just as likely to come from clinical failures as from clinical successes, and perhaps even more from investigations which have no immediate practical end in view. The paucity of these successes is perhaps responsible for the suggestion now and then made that chemotherapy is not living up to the expectations that were formed regarding it when its greatest achievement, salvarsan, was introduced into medicine now nearly twenty years ago. Conferences of learned societies are often useful as a means of gauging current impressions, and it is noticeable that at the present time such conferences dealing directly or indirectly with therapeutics are often much more concerned with the contributions made by biology and biochemistry than with those attributable to the study of chemotherapy. There are fashions even in science and in medicine.

It is all to the good, therefore, that a clinician like Dr. Kolmer should have been inspired to produce at this juncture the book now under notice. It puts on record the clinician's view, generously tempered by that of the laboratory worker—for Dr. Kolmer has the good fortune to fulfil both functions—of the present position and future prospects of chemotherapy in relation to clinical medicine. Throughout the book, indifference to, or an intimate and extensive knowledge of, the chemistry of synthetic drugs appears to be assumed, for this side of the subject is left severely alone, only two graphic formulæ, those of salvarsan and neosalvarsan, being given in the whole book. Those interested in chemotherapy can, however, well afford to dispense with such details, which are readily obtainable elsewhere.

The author's preoccupation with the treatment of syphilis and the important position which this disease naturally takes in any exposition of clinical medicine based on chemotherapy, accounts for the large amount of space, more than 600 pages, devoted to it, and bio-chemists and biologists will welcome this full discussion, especially of the possible and probable reactions of anti-luetic drugs in the body.

Perhaps the most interesting section of the book is that concerned with the chemotherapy of bacterial and mycotic diseases. It is well known that in spite of unremitting work in this direction, especially in Germany, and more recently in the United States, very little progress has been made, and it is difficult to decide whether the workers who persist in such investigations are long-sighted optimists or merely misguided enthusiasts. Dr. Kolmer discusses the methods of investigation available and the pitfalls which beset even the most wary in drawing conclusions from the results of experiments in these cases. He then deals with such progress as has been achieved in the use of dyes for local and general infections, ethylhydrocupreine and its relatives in the treatment of pneumococcal and other bacterial diseases, and finally with the compounds of such metals as mercury, copper, arsenic, gold, etc., which have been the subject of so many forlorn hopes for the cure of tuberculosis. The section gives a fair and unbiased account of what has been done, and in view of the generally discouraging results, Dr. Kolmer takes a surprisingly cheerful view of the possibilities of chemotherapy even in these diseases.

The section on trypanosomal diseases is made the means of a very thorough discussion of trypanocidal tests, which have become so important a part of chemotherapeutical work and a subject to which Dr. Kolmer has himself made valuable contributions.

The other sections are neither so full nor so up-to-date as the three just alluded to. Experts on tropical diseases will scarcely regard 25 pages as adequate for the discussion of malaria, even if it has only recently become amenable to chemotherapeutical investigation, or 30 pages sufficient to describe all the work that has been done with surprisingly successful results in some cases, in "leishmaniasis, amebiasis, piroplasmosis, schistosomiasis, and other protozoan and metazoan diseases of man and the lower animals." It seems odd that kala azar, for example, can be dealt with without mention of the valuable work done by Dr. Napier in India in clinical trials of antimonial drugs, which has led to great improvements in treatment in the last few years. Medical men, in writing about the treatment of malaria, generally contrive to suggest that the supplies of cinchona bark are inadequate, or that the price of quinine is too high, and Dr. Kolmer is no exception to this rule. The fact is that for some years cinchona bark was over-produced, and if this had been allowed to go on, many of the plantations would have gone out of existence. The planters in Java very wisely took steps to control output, just as British rubber-producing companies have had to reduce the output of rubber to avoid a similar catastrophe. To anyone who feels doubtful about the wisdom of such a course, the excellent address dealing with this subject which Sir Thomas Holland gave a short time ago to the Royal Society of Arts may be commended.

The book is very well produced, and contains few misprints or mistakes in chemical nomenclature; it can be cordially recommended to chemists and biologists concerned with chemotherapeutical work as affording the kind of information which is particularly difficult to obtain and collate, except by laborious search through medical literature. Dr. Kolmer not only provides this information, but also presents it with illuminating comments.

Physics for Students.

(1) *Physics for Colleges*. By Prof. H. Horton Sheldon, Prof. C. V. Kent, Prof. Carl W. Miller, and Prof. Robert F. Paton. Pp. vi + 655. (London: Macmillan and Co., Ltd., 1927.) 16*s*. net.

(2) *The Elements of Physics*. By Prof. Alpheus W. Smith. Formerly published under the title of "The Elements of Applied Physics." Second edition. Pp. xviii + 660. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1927.) 17*s*. 6*d*. net.

(3) *Light*. By F. Bray. Pp. xii + 284 + 6 plates. (London: Edward Arnold and Co., n.d.) 6*s*.

(4) *Light*. By Vivian T. Saunders. Pp. vii + 320. (London: John Murray, 1927.) 6*s*. net.

(5) *Studies in Optics*. By Dr. A. A. Michelson. (The University of Chicago Science Series.) Pp. ix + 176 + 7 plates. (Chicago, Ill.: University of Chicago Press; London: Cambridge University Press, 1927.) 10*s*. net.

IN spite of the multitude of text-books on physical science, there always seems room for the ingenious author to produce a new volume. Amongst the problems he has to solve is included that of finding a method of so presenting his subject as to maintain the interest of the reader; for all educational experts are agreed that the power of remembering what is read depends upon the degree of interest that is aroused in the mind. The element of wonder may be excited in various ways, and the books noticed below serve to illustrate some of the methods which may be employed. Another difficult question which confronts the author is that of determining to what extent recent investigations and modern theories should be treated, and if they are adopted, to know at what point in the exposition the new material or method is to be introduced. For example, in a work on electricity, should the electron theory be made the basis of the treatment, or should it be discussed separately after developing the older theory? The answer to such a question must obviously depend on the purpose in view and on the class of reader for whom the book is intended.

(1) Under the editorship of Prof. Horton Sheldon, this text-book of "Physics for Colleges" has been compiled by four authors, each one of whom is engaged in teaching physics in an American university. Each author has been responsible for one section of the book, and has tried to make it a continued story. Thus, in the editor's section on heat and molecular physics, the kinetic theory underlies the whole, and everywhere explanations are based on this. In the same manner the electron theory underlies the section on electricity and magnetism, and wave motion underlies that on sound and light. "This not only unifies each section but it weaves modern physics into the structure of the book instead of leaving it as a mere appendage." It is noteworthy that the authors have been able to include chapters on modern radiation theory, quantum theory, and other modern developments; although the treatment of such subjects is necessarily somewhat slight, it is certainly desirable that the student who includes physics in his college course should be made familiar with recent theoretical and experimental work.

The editor, who has had experience of teaching classes containing hundreds of students, makes one remark which may be laid to heart by writers of text-books: "An attempt has been made at every turn to minimise those things which tend to influence the student to memorise, and to magnify those things which tend to induce him to use logical methods of thinking. Thus italics, bold-faced type, etc., have been avoided in the body of the text, as the student usually tries to memorise such portions of a book."

(2) In making a minor change in the title of his text-book, Prof. Alpheus Smith has not altered either the purpose or the method of the work. It is intended for students who are primarily interested in the practical applications of physics, and the author has been very successful in illustrating such applications to agriculture, engineering, physiology, and everyday life. The method employed has involved some curtailment in the number of

scientific facts recorded, and special stress has not been laid on the historical development of the subject. In the revised edition, additional paragraphs have been provided on sound and light, with illustrative material taken from architectural acoustics, audition and voice sounds, and from the physiological effects of light. Finally, a fifth part has been added giving in concise form a clear and interesting account of the brilliant discoveries and advances made in physics in recent years. The illustrations are numerous and, in general, excellent; in a few instances, however, photographs of apparatus show only the external appearance, and details of construction are lacking. Of special excellence are the photographs of sound waves produced by bullets or electric sparks.

(3) Mr. Bray's book on light was begun when the author was a science master at Clifton College, and was designed to satisfy the requirements of a general education and to enable a boy to pursue the study of light in a logical manner up to the modern developments of the wave theory. The author has been successful in his aim of producing a readable text-book, and he is to be commended for having devoted so much attention to the historical side, which, as he points out, provides a wide field of interest and fascinates both old and young.

The first chapter is an interesting historical survey of the science of optics, and the account given of the theories of light put forward by the early Greek philosophers is suggestive when the reader is already familiar with the most recent theories of radiation. More detailed history accompanies the accounts of the important principles laid down in each chapter, and five full-page plates give portraits of distinguished discoverers in optics. There are numerous diagrams, and also a large number of experimental verifications and determinations. The chapter on optical instruments is of special value, and we note that Schuster's method of focusing the telescope and collimator of a spectrometer is described.

Part II., which forms about one-third of the volume, is concerned with the development of the wave theory and is prefaced by an elementary treatment of simple harmonic motion and wave motion. The chapters on interference, diffraction, and polarisation are well written, and we find a brief reference to Bohr's theory of the origin of spectra in the last chapter. In view of recent progress, the statement that very little is known of the 'band spectrum' should be revised in a new edition.

(4) Mr. Saunders, of Uppingham, has written a text-book on light of somewhat similar character to that by Mr. Bray, for students who are following an elementary but formal course. It is intended to cover the ground required for the usual school examinations, but as it was not considered necessary to give detailed instructions concerning laboratory experiments, the scientific information given and the method of treatment are slightly more advanced than in Mr. Bray's book. For example, in the chapter on photometry we find descriptions of the selenium cell and the photo-electric cell which are receiving much attention in photometric laboratories. It may be pointed out that a photometer head of the Lummer Brodhun type was described by Prof. William Swan of St. Andrews thirty years before its invention in Germany.

It is a little misleading to say of the Gregorian telescope that "the telescope was never actually set up." James Gregory first described his reflecting telescope in "Optica Promota" (London, 1663) at the age of twenty-four. The attempt which he made to get a telescope from the London optician Reive was abandoned because the figure proved so bad. That versatile genius Robert Hooke constructed the first Gregorian telescope, which was presented to the Royal Society in February 1674. It is interesting to find that in the previous year the University of St. Andrews had commissioned "Mr. James Gregorie, professor of the Mathematical Sciences here to go to London, and there to provide so far as the money already received from our Benefactors will reach, such instruments and utensils as he with advice of other skilful persons shall judge most necessary and useful for the above mentioned design [for providing ane observatory]." As Gregory was a friend and correspondent of John Collins, the secretary to the Royal Society, it is more than probable that he met Hooke, the curator, during his visit to London, and discussed the telescope with him. Later, several Gregorian telescopes were made by Short, and one of these is now in the Natural Philosophy Department of the University of St. Andrews, marked James Short, Edinburgh, 1736. The same form was generally employed in the eighteenth century.

The latter part of the book is devoted to the wave theory of light, with descriptions in the last two chapters of electromagnetic radiations and spectral series. The chart from "Phases of Modern Science," showing the great range of electromagnetic waves, is reproduced, and an interesting elementary account is given of Bohr's theory of the hydrogen atom.

(5) Prof. A. A. Michelson, who was included in NATURE's list of Scientific Worthies on Jan. 2, 1926, has done a valuable piece of work in giving a résumé, under the title "Studies in Optics," of his

own investigations on the subjects of interference, diffraction, and the determination of the velocity of light. His fertile mind, equipped with the necessary theoretical knowledge (derived largely from the work of the late Lord Rayleigh), seems to possess an almost uncanny power of translating ideas into practice. The book is based on the undulatory theory of light (the difficulties associated with the quantum theory being no more than hinted at), and it begins with a discussion of the interference of light waves and a description of the author's interferometer. Measurements of a small displacement made by this apparatus are from twenty to fifty times as accurate as the corresponding measurements by microscope or telescope. In the measurements of the standard metre in light-waves the accuracy may be expected to be of the order of one part in several million. The special case of interference known as diffraction is next discussed, and a word of praise must be given to the excellent photographs of diffraction patterns reproduced in the plates. The difficult problem of ruling large diffraction gratings has been attacked with marked success by Michelson, who applied interference methods to the measurement and correction of the errors of the dividing engine.

By the application of interference methods in astronomy it has been possible to measure not only the diameters of the satellites of Jupiter, but even the diameter of the red giant star Betelgeuse, which was found comparable with the diameter of the orbit of Mars. Experiments are still in progress at Mount Wilson Observatory to determine as accurately as possible the velocity of light, the value found from observations in 1926 being 299,796 kilometres per second. But it is probable that the negative result of the Michelson-Morley experiment will serve to perpetuate the fame of these experimenters even more than positive quantitative determinations. This zero result is the corner-stone of the theory of relativity, which is held by some to be incompatible with the existence of luminiferous ether. It is significant, however, that Michelson concludes his account of the theory by saying: "It is to be hoped that the theory may be reconciled with the existence of a medium, either by modifying the theory, or, more probably, by attributing the requisite properties to the aether; for example, allowing changes in its properties (dielectric constant, for instance) due to the presence of a gravitational field."

The University of Chicago is to be congratulated on this addition to its Science Series.

H. S. ALLEN.

The Constitution of Glass.

The Constitution of Glass: a Series of Papers reprinted from the Journal of the Society of Glass Technology. Edited by Dr. W. E. S. Turner. Pp. vii + 191. (Sheffield: Society of Glass Technology, 1927.) 7*s.* 6*d.*

IN May 1925 the Society of Glass Technology organised a general discussion to which papers on the nature and properties of glass were contributed by British, French, German, and American authorities. These papers have now been reprinted, with seven pages of "General Discussion on the Foregoing Papers," which are nine in number, since one additional paper appears to have been added to those contributed to the discussion. The volume also includes a paper on "The Viscous Properties of Glass," which was read at a meeting of the Society at the end of 1926, and a report on "The Structure and Constitution of Glass," by Dr. Rosenhain, prepared at the invitation of the Council under the Glass Research Association Trust Deed.

It is this last report that specially invites criticism, since, unlike the earlier papers in the present volume, it does not appear to have been read at a meeting of the Society for which it was prepared, and is therefore published without any accompanying discussion. This is an unfortunate limitation, since the theoretical views now advanced to explain the structure of glass and other amorphous solids gives the impression of having been devised (as indeed the author hints) in pre-War days, when the nucleus atom and the electronic origin of valency were alike unknown, and to have been brought only incompletely into conformity with the implications of these revolutionary doctrines.

Thus we find that the crisp distinction between the 'electrovalent' structure of common salt and the 'bonded' structure of integral molecules, for which the quantum theory supplies such ample justification, is replaced by an amorphous conception of bonds of varying strength and varying length, uniting all the atoms in the mass, with little or no regard to the ordinary laws of chemical combination. This formless picture is rendered rather more confused by the fact that, although the relative constancy of length of the bonds between the atoms is scrapped, the fixity of angles is retained; but a final element of bewilderment is created by an assertion that, when an alkaline silicate is electrolysed, "rupture of bonds between an alkali metal and oxygen must have occurred," since the word "must" is surely too strong to use when postulating a rupture of bonds which the modern theory of 'complete ionisation' supposes to be non-existent!

The general reader will welcome the reproduction of a paper on the equilibrium diagram of the soda-lime series of silicates, from the Geophysical Laboratory at Washington, and of a summarising paper on the structure of quartz by Sir William Bragg; and chemists will add this volume to their shelves all the more readily because it is issued in the familiar format in which the *Journal of the Chemical Society* has appeared for more than half a century, and has therefore become by long usage an ideal for chemical publications when the financial assistance of the advertiser is not essential.

Our Bookshelf.

(1) *Applied Magnetism.* By Dr. T. F. Wall. Pp. 262. (London: Ernest Benn, Ltd., 1927.) 28*s.* net.

(2) *Einführung in die Elektrizitätslehre.* Von Prof. R. W. Pohl. Pp. vii+256. (Berlin: Julius Springer, 1927.) 13·80 gold marks.

(1) DR. WALL gives a good general survey of the subject of applied magnetism and of the theoretical aspects of certain of the questions raised by recent developments of magnetic practice. The bulk of the work is devoted to the problem of obtaining practical control over the magnetic behaviour of the materials used in practical engineering work and to a description of the methods employed in testing the magnetic behaviour of such materials; and the author's own work and experience enable him here to give a tolerably complete, if not always a critical, account of the present state of our empirical knowledge of a now very extensive subject. The treatment of the theoretical parts of the subject is less happy, being both incomplete and, in places, confused; but as this side of the subject is still in a state of flux, this cannot be regarded as detracting seriously from the merits of an otherwise good book.

(2) This book, of a very different calibre from Dr. Wall's volume, is intended mainly as an introductory text-book of electricity and magnetism for students who are out for the ideas rather than their mathematical or technical development, and have to approach them experimentally. It covers the whole range of the subject from electrostatics and magnetostatics, through the usual ideas of current generation and flow, to electrodynamics, radio-activity, and electric waves, with all the thoroughness that is possible within the scope of its number of pages. The treatment is experimental throughout, each idea being derived from the result of an experiment, and suggesting further experiment, and so on throughout the whole subject; but an excellent balance is maintained between the details of the experiments and the description of the facts which emerge from them. Altogether this is a delightful book, one of the most pleasant features of which is the large number of beautiful illustrations, diagrammatic and photographic, which adorn almost every page.

G. H. L.

Properties and Testing of Magnetic Materials. By Thomas Spooner. Pp. xiv+385. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1927.) 25*s.* net.

NEARLY every piece of electrical apparatus has, as Mr. Spooner points out, a magnetic circuit. In the majority of cases this circuit is the governing factor which decides the size, shape, weight, and cost of the apparatus; a knowledge of its laws and the materials from which it may be constructed is therefore very desirable on both technical and economical grounds. Unfortunately, to those not already familiar with magnetic theory, the whole subject is somewhat repellent and irksome. The unlovely names of units and properties (which to the beginner appear far too numerous), the lack of uniformity among different authorities, and a feeling that the whole subject is not quite free from a tinge of empiricism, are among the probable reasons for this state of things. Anyone who feels like this will welcome Mr. Spooner's book.

The introduction gives the ordinary relations and formulæ of the magnetic circuit in very clear and convincing outline, and a useful comparative table of the various units of magnetic induction. The remainder of the first half of the book is a complete résumé of our present knowledge of the magnetic properties of commercial ferro-magnetic materials. The results of researches made by workers in many countries are given very fully, and these are discussed and compared with the author's own experiments. The book is therefore by no means a mere compilation. A very large amount of quantitative information is given—almost every page has a graph from which numerical values may easily be read off. The effects of composition, heat treatment, crystalline structure, etc., are shown, and problems introduced by modern high-frequency apparatus receive consideration.

The second part of the volume is devoted to a complete survey of the apparatus and methods of magnetic testing, with chapters on core losses in commercial machines and on magnetic analysis.

A. L. R.

A Manual of Automatic Telephony. By Charles W. Wilman. (Lockwood's Manuals.) Pp. vii+223. (London: Crosby Lockwood and Son, 1927.) 7*s.* 6*d.* net.

THE average technical student finds great difficulty in mastering the theory of the working of automatic telephony. In our opinion, this is due to the fact that nearly every book on the subject begins at once by describing in detail some complete automatic system, and the student is lost in what appears to be a hopelessly complicated maze of circuits. Mr. Wilman has appreciated a beginner's difficulties, and so begins with a few simple general considerations before describing the uses of the various devices used in practice. The diagrams given are very clear, all unnecessary details being omitted, and so the student will have little difficulty in seeing how an automatic system works.

Manual systems in the past have given satisfaction, but there are several advantages in connexion with automatic systems which make them more desirable. For example, connexions can be completed more quickly and can be released instantaneously. Errors due to incorrectly hearing a number are eliminated. There is a large saving in operators' salaries. A twenty-four hours' service can be given in every exchange, and so a large number of small exchanges can economically replace a large exchange. In countries where several languages are spoken, a call may be completed with equal facility whatever language the subscriber speaks. As for many years to come automatic and manual exchanges must exist side by side, the author devotes a chapter to explaining how they can be interconnected. We recommend this book to all readers who want to get an elementary knowledge of the working of an automatic system.

Some Famous Medical Trials. By Dr. Leonard A. Parry. Pp. x + 326. (London: J. and A. Churchill, 1927.) 10*s.* 6*d.* net.

This entertaining work contains an account, from the time of Elizabeth to the present day, of thirty odd trials in which medical men figured, usually as defendants. The cases, which, as the author acknowledges in the preface, have not been arranged in any particular order, either chronological or alphabetical, have, with two exceptions from France and the United States respectively, been taken from the criminal annals of Great Britain. Ten cases in which the medical man was brought to trial for treason or other political offences contain nothing of scientific interest, and the same may be said of the crimes of violence, libel, and poisoning. The most instructive cases are those dealing with poisoning, the drugs chosen by the doctors for their victims being arsenic, aconite, hyosine, strychnine, and morphia. Among these may be cited the first case of poisoning by morphia, in which the evidence of Orfila, the celebrated Parisian toxicologist, was the cause of bringing the poisoner, Dr. Edmé Castaing, to the guillotine. Mention may also be made of an interesting chapter on the 'resurrection men,' dealing with the events which gave rise to the amendment of the law with regard to the supply of bodies for anatomical schools and the passing of the Anatomy Act.

Roman Britain. By Gordon Home. (Benn's Sixpenny Library, No. 4.) Pp. 80. (London: Ernest Benn, Ltd., 1927.) 6*d.*

Mr. Gordon Home's account of "Roman Britain" in Messrs. Benn's attractive little "Sixpenny Library" is a model of concise popularisation. Apart from the many difficulties and obscurities which are involved in the study of the period of Roman occupation in Britain, the necessary concentration on technical details in the reports of excavations, and the lack of a comprehensive historical background, have militated against popular interest in this important element in the composition of the cultures of Britain. This is notwithstanding the fact that discoveries relating to the Roman occupation are more frequent and usually tell more than those of any other period of the early history of Great Britain. Mr. Home has provided exactly the background that is needed to promote such an interest. He tells a clear consecutive story in which, without shirking difficulties, he has given a reasonable interpretation, while avoiding controversial details which might confuse his readers as well as be irrelevant to his main purpose. The stress he lays on purely British culture and its gradual interpenetration by Roman influence, as well as the view taken of the state of the country at the close of the occupation, are useful correctives of popular misconception.

Adventures of Exploration, Book 6: North America. By Sir John Scott Keltie and Samuel Carter Gilmour. Pp. iv + 228. (London: George Philip and Son, Ltd.; Liverpool: Philip, Son and Nephew, Ltd., n.d.) 2*s.* 6*d.*

The volume on North America, which is slightly larger than the earlier volumes, completes this admirable series. Some fifteen notable journeys have been retold without the omission of any important facts and illustrated by carefully chosen pictures from many sources. Each tale has a small sketch map to itself, which are excellent examples of clear maps, with no more names than are needed to follow the text. The voyage of Jacques Cartier begins the book, which goes on to tell among others of Champlain, La Salle, Hudson, Hearne, Mackenzie, Lewes and Clark, Franklin, Peary, Erichsen and Mikkelsen. It is not a complete history of North American exploration, and is not intended to be such, but it is an admirable sketch of the chief stages in the story, and is bound to quicken interest in geography.

The Diary of Henry Teonge, Chaplain on Board H.M.'s Ships Assistance, Bristol, and Royal Oak, 1675–1679. Transcribed from the original manuscript and edited, with an Introduction and Notes, by G. E. Manwaring. (The Broadway Travellers.) Pp. x + 318 + 8 plates. (London: George Routledge and Sons, Ltd., 1927.) 12*s.* 6*d.* net.

When Teonge's diary was first published in 1825, some doubt was cast on its authenticity. The disappearance of the manuscript made it difficult to answer the criticisms, but its rediscovery has now set all doubts at rest. The present edition has been produced from the original manuscript with modernised spelling and a number of notes. The author served as a chaplain in the Mediterranean. In addition to a vivid picture of life in the Navy in the seventeenth century, there are interesting accounts of inland journeys in Syria and Palestine. The book is beautifully produced and illustrated with a few contemporary drawings and engravings, but a track chart might well have been added.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Earth Currents and Terrestrial Magnetism.

The study of a monograph on earth currents by Dr. D. Stenquist,[1] telegraph engineer, published in 1925 in Stockholm, suggests that telegraphists have it in their power to add much to our knowledge. The early observations by W. H. Barlow and C. V. Walker showed that an intimate connexion exists in England between magnetic storms and disturbances in telegraph lines, and similar observations elsewhere showed this to be a general phenomenon. So much is this the case that the authorities of the Ebro Observatory, Tortosa, accept as their quiet days for the study of the regular diurnal variation of earth currents the international magnetic quiet days selected at De Bilt, provided their records for these days are complete. Further, Messrs. W. J. Peters and C. C. Ennis, of the Carnegie Institution of Washington, have shown that the Ebro earth current data exhibit in a similar way to magnetic data, and to a similar degree, what is known as the 27-day interval, representing, it is believed, the rotation period of the sun's equatorial surface.

Dr. Stenquist gives a variety of statistical data having an intimate bearing on the subject. In particular, attention may be directed to his Table I., p. 26 *l.c.*, giving a total of 53 dates between Nov. 1, 1906, and Oct. 31, 1909, on which a current of at least 15 milliamperes was observed in the central telegraph station at Stockholm. According to Stenquist, this is the smallest current causing serious telegraphic disturbance. As is now pretty generally known, yearly lists are issued from De Bilt giving for each day a magnetic character varying from 0·0 (very quiet) to 2·0 (very highly disturbed). These figures are based on returns from some 30 to 40 magnetic observatories in different parts of the earth. An analysis of these international character figures for the 36 months covered by Stenquist's table led to the following results :

A	2·0	1·9	1·8	1·7	1·6	1·5	1·4	1·3	1·2	1·1	1·0	<1·0
B	6	4	13	10	14	8	27	25	32	61	71	825
C	6	4	10	6	4	2	5	4	2	3	5	2

A is the international character figure ; *B* the total number of days having each specified character within the 3 years ; *C* the number of these days included in Stenquist's table. The two days on his list with characters less than 1·0 were Oct. 11, 1907, with 0·6, and Oct. 20, 1909, with 0·8. A high value of an earth current may persist for only a short time, while the magnetic character represents the day as a whole. A short portion of a day of character 1·0 *might* be more disturbed than any portion of another day of character 1·5. Thus it was not to be expected that all the days on Stenquist's list would have very high character figures.

What, however, is really significant is that the 23 days of the three years which had magnetic characters of 1·8 or more supplied 20 of the 53 days on Stenquist's list, while the 504 days with characters of 0·5 or less supplied none. It is obvious that if data such as Stenquist's were available for different parts of the world, especially if the directions of the lines in which the high currents prevailed were known much might be learned as to the prevalence of outstanding earth currents in different regions. A day of high magnetic character is certain to have been highly disturbed magnetically all over the world. But in general the amplitude of disturbance is larger and rapid oscillatory changes are more in evidence in high than in low latitudes. Further, in high latitudes large disturbance is usually in evidence at the same time in all the magnetic elements, whereas in low latitudes disturbance is often mainly confined to the horizontal force. It is obviously important to know from actual observation what the corresponding facts are as regards earth currents.

Richmond, Surrey.

Light and Sight.

In the article, "Light and Sight," which appeared in Nature of Jan. 21, Sir John Parsons accepts as evidence "that the human eye has become specially adapted to sunlight," "the fact that the brightest part of the spectrum, as seen by the light-adapted eye, coincides more or less accurately with the summit of the curve of radiant energy." The implication that the eye has developed in the direction of maximum efficiency as a converter of energy justifies careful examination of the suggestion.

The coincidence in question involves at least three quantities—the sensitiveness of the eye, the amount of solar radiation reaching the earth's surface, and a quantity which serves to define the quality of the radiation. In "the curve of radiant energy" to which Sir John Parsons alludes, the third quantity, the abscissa of a point on the curve, is presumably the wave-length of the light. It is not irrelevant to consider whether the coincidence would be maintained if some other variable were substituted for the wave-length, and, if it should not be maintained, whether special significance can properly be attached to the coincidence observed when this particular variable is adopted.

Physicists will probably have little hesitation in saying that if, in such a connexion, one variable is of greater significance than another, that variable is not the wave-length of the light, but its frequency. The widespread use of wave-lengths is attributable to the convenience, in the experimental analysis of light, of employing apparatus which can be effectively calibrated by measurements of length alone, rather than to any theoretical advantages consequent on this usage. If now we substitute frequency for wave-length, the brightest part of the spectrum on the new basis will suffer a small change, but the highest point of the new energy curve (at least if we may regard the sun as a 'black' body) will lie well outside the limits of the visible spectrum. To me this fact appears conclusive evidence that the utilisation of the greatest possible amount of energy is not the factor which has led the human eye to utilise the particular spectral region to which we find it sensitive, and that the coincidence referred to is fortuitous.

An alternative suggestion may be offered. Many readers of Nature will recall Prof. R. W. Wood's remarkable landscape photographs taken, some with infra-red light only, and others with ultra-violet light only. The former are notable for the strength of the reflections from directly illuminated surfaces and the blackness of the shadows ; the latter for want of contrast amounting almost to general fog. These effects are due to properties inherent in the light itself; they are not manufactured by the photographic plates. Corresponding effects would be present were vision excited by these radiations. It is not unreasonable to suppose that any appreciable extension of the visible spectrum at the short wave-length end would impair rather than improve the clarity of the pictures we should perceive. On the other hand, we may suppose that, under more primitive conditions, life would have been rendered more precarious by the increased difficulty of observing enemies lurking in shadows, had there been any considerable shift of the mode towards longer wave-lengths.

---

[1] "Étude des courants telluriques." Mémoires publiés par la direction générale des télégraphes de Suède.

There is another coincidence mentioned in the article which may conceivably be accidental. This is the correspondence between the diameters of the retinal cones at their bases and the resolving power of the eye. We may note in passing that close agreement between these lengths would tend to discredit the theory which refers the limit of resolution to the fineness of retinal structures, rather than support it. At least three successive cones must be involved, on this view, in the resolution of two near point images, the total energy falling on the middle cone being appreciably less than that received by either of the outer cones. If we consider curves giving the energy distribution in the diffraction pattern of two sources when resolution is just possible, such as those given by the late Lord Rayleigh, we can readily appreciate that a decided fall in intensity at the centre of the pattern from the peak values is not inconsistent with the reception by the central cone of greater total energy than by each of the outer cones on which the most brilliant parts of the image are formed.

The chief reasons, however, for hesitation in accepting this theory are, on one hand, that it is unnecessary to seek for any explanation of a limit of this angular magnitude in the structure of the retina, for it is imposed by the wave-length of the light to which the eye is sensitive in conjunction with the diameter of the pupil; and on the other hand, that experiments in which this physical limitation does not arise yield figures which suggest that the eye possesses powers of discrimination much more refined than these coarser features of the retinal structure would lead us to expect. Illustrations of these finer ocular powers are afforded by the appreciation of form, the ability to set two straight lines to form a continuous line,[1] and the judgment of distance in binocular vision. Various explanations of these effects may be offered, but the observations at least entitle us to suspend judgment on the relevancy of this coincidence until more rigorous experiments enable us to discriminate between various views in the light of fuller knowledge.

T. SMITH.

The National Physical Laboratory,
Teddington, Middlesex,
Jan. 24.

I WAS aware of the highly speculative nature of the explanation of the apparent coincidence of the brightest part of the spectrum with the summit of the curve of radiant energy, plotted with wave-lengths as abscissæ, and I fully appreciate the validity of Mr. T. Smith's arguments. It is essentially a physical problem, and I am glad that my rash statement has aroused the attention of a physicist.

On the other hand, I dealt somewhat at length in my lectures with the problems of the *minimum separabile* and contour discrimination. I came to the conclusion that while the facts relating to the former were not inconsistent with a purely physical explanation, those relating to the latter could not thus be explained at present, but were at least rendered intelligible by physiological and psychological interpretations.

These considerations emphasise the complexity of visual phenomena, and the necessity for the co-operation of physicists, physiologists, and psychologists in their elucidation. Mr. Smith's letter is a welcome indication of the increasing interest which physicists are displaying in the physiological implications of their researches. J. HERBERT PARSONS.

The Excitation of Spectra by High Frequency Oscillations.

IN a recent letter to NATURE (Nov. 19, p. 726), Mr. J. R. Clarke gives a brief account of some experiments he has made on the excitation of various spectra in mercury vapour. The wording of his note suggests that he attributes the phenomenon cited to the relative shortness of the wave-length of his oscillating system (300 metres). The apparatus he uses is no other than the ordinary one of electrodeless discharge of which the spectroscopic interest has been clearly shown by Prof. E. Bloch and M. L. Bloch (*Journal de Physique*, 4, 333; 1923), whose first experiments were made with mercury in the absence of air, which is useless and even derogatory to obtaining pure spectra. This method has often been used since by these authors and others, most frequently, it is true, with damped oscillations, but M. Balasse recently employed undamped waves of about 155-880 metres (*Comptes rendus*, 1005; 1927) for the excitation of spectra of alkali metals. It may therefore be said that the method described is not merely full of promise, but also that it has already realised all these expectations.

Like the other kinds of discharges, the electrodeless discharge more or less weakens certain lines and strengthens others: in this way, in the case of mercury, the long list of arc lines given by the above-mentioned authors does not show a single line of the *mp* series, of which the strongest lines are, moreover, infra-red and red. This fact, found also by Mr. Clarke, is to be attributed to the kind of discharge employed and not to the shortness of the wave-length.

I have been studying for some time in this laboratory the emission of mercury vapour under the action of very much higher frequency waves, the period of which reaches the order of magnitude of the duration of life of the excited states of the atom. I have ascertained that a λ = 1·90 m. oscillator, of very feeble power (20 watts max.), produces an exceedingly brilliant electrodeless discharge in a slightly warmed quartz tube which has been exhausted with great care and sealed after a drop of mercury has been introduced by distillation. The luminous efficiency of this mode of excitation seems to be very high. This tube also lights along Lecher's wires at the maxima of the electric field. I obtained ordinary electrodeless arc spectra, with one or two enhanced lines, the feeble power of the oscillator not enabling me to obtain more. The line 2537 seems to be relatively very strong, but, up to now, I have not observed in these spectra any effect that could be attributed to the shortness of the wave-length. Besides, it is to be noticed that this mode of excitation seems to be extremely sensitive to the presence of organic impurities: a tube with aluminium electrodes which has been carelessly exhausted, although sufficiently so to give only the green fluorescence of glass when connected to an induction coil, emits close to the oscillator a bluish glow, containing the characteristic bands of carbon impurities and hydroxyl.

---

[1] See "The Unaided Eye," by J. W. French *Trans. Opt. Soc.*, 21, 127; 1919-20.

For the moment, I have given up the use of these 1·90 m. waves and have built a 5-10 metre wave-length oscillator (about 80 watts), in order to see how the growing pressure of the mercury vapour modifies the spectra obtained. I use either the electrodeless discharge or a discharge with only one electrode (in a different apparatus). In the latter case, in a suitable apparatus, permanently evacuated and provided with a liquid air trap, this projects a glow the length of which may attain 40 cm. The pressure of the mercury vapour is varied by heating the mercury, and the degree of excitation by varying the distance between the electrode and the oscillator. I obtain in this way spectra which depend on the pressure and degree of excitation, and the one-electrode discharge does not give results quite identical with those of the electrodeless discharge. At 80°-90°, for example, the former does not clearly reveal the unclassified lines which Mr. Clarke mentions, except perhaps the line 2540. This fact is peculiarly striking for the line 3984·1; this line shows itself very feebly even in long exposures, though it is strong in the ordinary arc. The unclassified lines are found, however, in the electrodeless discharge. In the one-electrode discharge, the glow is observable in the region where the mercury condenses: it is violet; I was unable to discern any impurity, but found that the red lines 6234·35, 6123·46, and 6072·64 were strong in this light. The spectrum of the whole of the glow, taken longitudinally, shows a strengthening of the series $1P - mD$ and $1P - mS$; this is a pressure, and not a wave-length effect. At a higher temperature (110°-120°) and feeble excitation, I get a green glow which shows the Lord Rayleigh and Volkringer spectra (*Proc. Roy. Soc.*, A, 114; 1927. *Comptes rendus*, 1927, *passim*). I am continuing the study of the development of these spectra at increasing pressure, but, at the above-mentioned temperature, I find in this glow the yellow line 5790·6 ($1P - 2D$), and the violet line 4347 ($1P - 3D$), which does not agree with Mr. Clarke's observations: he only saw the triplets s and d. Mr. Clarke, however, does not say what was the pressure of mercury vapour in his experiment.

Briefly, the method described by Mr. Clarke is the well-known one of the separation of spectra by the electrodeless discharge. I am trying to see if this and the one-electrode method, used with very short wave-lengths (1·90 metres and 5-10 metres), give new results. Up to now, I have not noticed any modification in the emitted wave-lengths, which was to be expected, and the relative alterations in the intensity of the lines are effects of pressure or strength of excitation, and not to be attributed to the shortness of the wave-length used.

M. Ponte.

Laboratoire de Physique de l'École
Normale Supérieure, Paris.

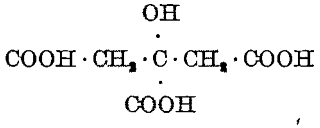
The Formation of Citric Acid by *Aspergillus niger*.

In two recent publications (*Jour. Chem. Soc.*, 200, 3044; 1927) we have presented results which are in agreement with the assumption that the conversion of glucose to citric acid by *Aspergillus niger* proceeds according to the scheme: glucose ⟶ gluconic acid ⟶ saccharic acid ⟶ citric acid.

It was suggested by Franzen and Schmitt (*Berichte der Deutschen Chem. Ges.*, 58, 222; 1925) that the precursor of the citric acid of plants is β-γ-diketoadipic acid, arising from saccharic acid by loss of water. They showed that the ester of the diketo-acid is easily converted to citric acid by alkali hydroxide, a transformation of the benzilic acid type:

$$\mathrm{COOH\cdot CHOH\cdot CHOH\cdot CHOH\cdot CHOH\cdot COOH} \xrightarrow[-2\mathrm{H_2O}]{}$$

$$\mathrm{COOH\cdot CH_2\cdot CO\cdot CO\cdot CH_2\cdot COOH} \xrightarrow[+\mathrm{H_2O}]{}$$



$$\mathrm{COOH\cdot CH_2\cdot \overset{OH}{\underset{COOH}{C}}\cdot CH_2\cdot COOH}$$

This observation strongly supports their view, but, apart from the recognition of diacetyl $\mathrm{CH_3\cdot CO\cdot CO\cdot CH_3}$ (a decarboxylation product of diketoadipic acid) in ethereal oils, no further evidence has been adduced in favour of the participation of the diketo-acid in citric acid synthesis either by higher plants or by moulds.

Owing to the instability of diketoadipic acid, experiments on its behaviour to *A. niger* are not yet completed. Meanwhile, it appeared probable that useful indications on this point could be obtained by studying the growth of the mould on adipic acid. One of us (T. K. W.) has shown that *A. niger* readily oxidises certain fatty acids in the β-position, and therefore might be expected to convert adipic acid to the β-γ-diketo-derivative:

$$\mathrm{COOH\cdot CH_2\cdot CH_2\cdot CH_2\cdot CH_2\cdot COOH} \longrightarrow \mathrm{COOH\cdot CH_2\cdot CO\cdot CO\cdot CH_2\cdot COOH.}$$

If the mould is capable of effecting a 'benzilic-transformation' the production of citric acid might then be expected. This has now been demonstrated. Potassium citrate has been isolated from cultures of *A. niger* on the potassium hydrogen salt of adipic acid, and on potassium muconate,

$$\mathrm{COOK\cdot CH:CH\cdot CH:CH\cdot COOK,}$$

and characterised as the tri-*p*-nitrobenzyl ester in each case. In the adipic acid experiment thallous citrate was also prepared and analysed. The muconic acid may give rise to citric acid by addition of two molecules of water forming β-γ-dihydroxyadipic acid,

$$\mathrm{COOH\cdot CH_2\cdot CHOH\cdot CHOH\cdot CH_2\cdot COOH,}$$

which on oxidation could yield the diketo-acid and finally citric acid. The conversion of fumaric and crotonic acids in the presence of liver tissue to malic and β-hydroxybutyric acids (Dakin, "Oxidations and Reductions in the Animal Body," pp. 49-50) indicates the biological possibility of this suggestion.

The conceivable formation of citric acid from muconic acid by addition of four hydroxyl groups and formation of saccharic acid receives less support from the biological side. Further work is in progress which, it is hoped, may enable the mechanism of citric acid formation from carbohydrates and organic acids to be definitely elucidated.

Extension of the Irregular Doublet Law.

Recent work in this laboratory has shown that the irregular doublet law, first discovered in 1920 by G. Hertz in the X-ray region, and since then extended by Millikan and Bowen for the optical region, is capable of much wider application. Millikan and Bowen have applied the law for the prediction and identification of spectra of atoms which are stripped to one or two valency electrons by vacuum discharge, and in the case of higher valence elements, for inner transition lines. But the law can be applied for the prediction of spectra of elements with a larger number of valency electrons giving rise to complicated spectra. The extension of the law in its most general form can be thus enunciated :

If we compare the spectra of a group of successive elements which are reduced by electric discharge to the same electronic constitution (for example, C, N^+, O^{++}, Fl^{+++}, N^{+4}), then frequencies of corresponding lines arising out of a transition in which the total quantum number remains unchanged will form an arithmetic progression.

The law can be very easily illustrated with the atomic chart given by one of the authors (*Phys. Zs.*, p. 470 ; 1927).

$$\begin{array}{ccccc} K_1 & & & & \\ 2 & & & & \\ & L_1 & L_2 & & \\ & 2 & 1 & & \\ & & M_1 & M_2 & M_3 \\ & & [1] \rightarrow & (1) \rightarrow & (1) \end{array}$$

In this chart, horizontal transitions refer to $\Delta n = 0$. Thus taking C, N^+, O^{++} . . . we find that the origin of all possible groups of lines can be visualised as follows :

$$L_2L_2 \rightarrow L_2M_1 \rightarrow L_2M_2 \rightarrow L_2M_3$$
$$(M_1 \rightarrow M_2) \quad (M_2 \rightarrow M_3)$$

Now the corresponding lines of the successive elements arising out of the transitions

$$L_2M_1 \rightarrow L_2M_2, \text{ that is, } ({}^3P, {}^1P) - \begin{pmatrix} {}^3D, {}^3\bar{P}, {}^3S \\ {}^1D, {}^1\bar{P}, {}^1S \end{pmatrix} \text{ lines,}$$

and

$$L_2M_2 \rightarrow L_2M_3, \text{ that is, } \begin{pmatrix} {}^3D, {}^3\bar{P}, {}^3S \\ {}^1D, {}^1\bar{P} \; {}^1S \end{pmatrix} - \begin{pmatrix} {}^3\bar{F} & {}^3\bar{D} & {}^3P \\ {}^1\bar{F} & {}^1\bar{D} & {}^1P \end{pmatrix}$$

will form arithmetic progressions.

Application of this law can be extended to all other complicated spectra.

It follows that if the spectra of two elements, preferably successive, of any group be known, it becomes quite easy to predict the spectra of the remaining elements.

In the group just mentioned, namely, C, N^+, O^{++} . . . the spectra of N^+ has been completely elucidated by Fowler and Freeman, and that of O^{++} is nearing completion thanks to the work of Mihul. (Mihul's levels are wrongly given, though his multiplets are correct. They can be easily reshuffled and correctly fitted to Hund's theory). We can then predict the spectra of C, which is still unknown. Then $L_2(M_1 \rightarrow M_2)$, as well as $L_2(M_2 - M_3)$ lines which are next in intensity to the fundamental $L_2L_2 \rightarrow L_2M_1$ $({}^3P,\ {}^1\bar{D}\ {}^1S) - ({}^3\bar{P}, {}^1\bar{P})$ lines are found to be beyond 8000 A.

In a similar way, spectra of all groups can be predicted and correctly located.

The Scattering of Wireless Waves.

OBSERVATIONS made during the past year have brought to light a new factor which plays a very considerable part in wireless transmission on short waves, say between 14 and 50 metres. This factor is a very pronounced scattering of the wireless waves from the upper regions of the atmosphere or Heaviside layer.

The existence of this scattering has been brought to light by the use of various types of direction-finding apparatus. The results obtained by the use of these indicate that the energy received at distances beyond the reach of the direct ray, say greater than 100 km., is either partially or wholly scattered. The scattering effect is most marked within the 'skip distance.' As is now well known, the main rays from a short wave transmitter find their target at distances greater than about 200 to 500 miles, these distances depending on the wave-length, season, and time of the day. It is found that the intervening region (between the range of the direct ray and the end of the skip distance) is almost wholly illuminated by scattered radiation, which, being more or less isotropic, gives no indication of direction. Precautions have been taken to eliminate the reflected wave polarised with its electric force horizontal, which on the longer wave direction finders is responsible for directional errors and absence of bearing. The effects observed, therefore, on the short waves cannot be due to this cause.

During the summer months the scattered radiation appears to be more or less isotropic, but recently we have found evidence of anisotropic scattering, which suggests that it is akin to the scattering of light from the sky, so that it is probably partly or wholly polarised in a direction perpendicular to the direction of the incident ray.

Even at long distances the main ray appears to be associated with some scattering estimated to be 1/6 to 1/10 of the amplitude of the main signal. This scattering is a factor on all waves between 14 and 50 metres. The range above this has not been thoroughly investigated, and there appears to be no evidence of scattering in the longer wave band used for broadcasting.

These facts might indicate that the scattering follows Lord Rayleigh's law, increasing as the fourth power of the frequency, except that there is not sufficient numerical evidence to show that it varies in this manner between 50 and 14 metres. Indeed casual observation might indicate that there was very little variation of the scattering ratio in this range.

On the other hand, it may indicate that the mesh of the scattering structure is small compared with lengths of 300-400 metres, but is large compared with 50 metres.

Whatever other conclusions we may draw from this evidence, it seems certain that the Heaviside layer is by no means a uniformly ionised region, but is very patchy, and there is some evidence of the existence of clouds which are small in dimensions compared with the shortest wave-length, that is, 14 metres.

New Edition of Willard Gibbs's Works and Proposed Commentary.

IN 1906 the writings of Willard Gibbs were printed in a collected edition of two volumes entitled "The Scientific Papers of J. Willard Gibbs." Vol. 1 contained all of his papers on thermodynamics, and Vol. 2 the remainder of his published writings with the exception of the book "Elementary Principles in Statistical Mechanics," which had been published only five years earlier and was at that time still available. At the present time both Vol. 1 of the "Scientific Papers" and the volume on statistical mechanics are out of print.

In connexion with a movement started last winter to establish at Yale University a memorial in honour of Willard Gibbs, provision has been made, through the generosity of a donor who prefers to remain anonymous, for a new and complete edition of Willard Gibbs's writings. This will consist of either two or three volumes, well printed and bound, and will be sold at a very moderate price to encourage a wide distribution. It will probably be published during 1928.

In addition to this reprinting of the original text of Gibbs's works, it is proposed to publish, at some later date, a volume or volumes designed to aid the reader to bridge the well-recognised gap between Gibbs's theorems on one hand, and the actual experimental data of the chemist and physicist on the other. This supplementary material, to be written by competent authorities in the several fields, would aim (*a*) to explain the philosophical background of Gibbs's method; (*b*) to amplify the treatment of points of special difficulty; (*c*) to discuss the evaluation of Gibbs's functions in terms of directly measurable quantities; and (*d*) to furnish a variety of illustrative examples from the literature now available. Such treatment is most needed in the case of the thermodynamic papers, but the plan may be extended to cover Gibbs's writings on other subjects if it seems expedient. The financial support of the undertaking has been liberally provided for, and suitable honoraria will be paid to the authors of the new material.

The undersigned committee, appointed to study this plan, earnestly solicits suggestions and comments from all persons interested, especially with respect to any or all of the following questions:

1. Which of the aims outlined above are the most important?
2. How should the subject matter be subdivided into parts which can be handled by a single author?
3. What persons, irrespective of nationality, are best fitted by ability and training to undertake these different parts?

Letters containing suggestions or criticisms will be welcomed, and may be addressed to the Gibbs Committee, Sterling Chemistry Laboratory, New Haven, Conn.

Use of Diffraction Effects in Measurements of Stellar Photographs.

The central area of the image of a star in stellar photographs consists of a cluster of silver granules disposed radially in rapidly decreasing numbers, so that the circular or nearly circular boundary is ill defined. This want of definition is necessarily responsible for a large part of the probable error in the microscopical measurements of the star's co-ordinates.

The images of the brightest stars in some photographs, however, may be observed to be accompanied by radial 'rays,' which proceed outwards from both ends of a diameter of the disc as a narrow band gradually terminating in a vanishingly thin line. These effects are well known to be due to diffraction, and it appears that this occasional defect in the image might be purposely produced and used to increase the accuracy of measurement.

If a thin wire be stretched across the aperture of the object glass of the telescope, a star image when observed with an eyepiece will be crossed by a series of narrow spectra at right angles to the direction of the wire, and presumably the central line of this narrow band of interrupted light passes through the point of maximum intensity in the star image. The closer the wire is to the eyepiece the shorter the spectra become, and finally they vanish when the wire coincides with the image. The same narrow band of light is produced when the wire is placed outside the telescope between the object glass and source.

The effect is not altered by moving the wire in a direction perpendicular to the optic axis, and is still apparent when the wire is just within the boundary of the refracted bundle of light; and therefore the presence of other wires parallel to the first only increases the amount of light diffracted into the narrow band of spectra.

It is obvious that if two gratings be constructed of parallel thin wires and crossed at right angles, the images of stars photographed through them will be crossed by two narrow lines at right angles to one another.

It is conceivable that the micrometer wires of the reading microscope may be set with smaller probable error on the central line of these narrow bands than on the centre of the ill-defined star image itself. It is also possible that the presence of a binary will be more readily perceived by the doubling of the bands than by observation of the confused disc itself, but I have not been able to try this yet. I shall be grateful if any astronomer can inform me if this method has been used for the purposes of measurement.

It may be noted that if a wire or a couple of parallel wires be placed between the object glass and eyepiece of a microscope, the focus of a star-image can be more readily determined than by observation of the ringed disc alone. The very fine narrow band of diffracted light crossing the centre of the disc passes more rapidly in and out of focus than can be observed with the central spot of the disc itself.

Altered Character in the White-faced Spanish Fowl.

A rumour gained currency last year that the old white-faced Spanish fowl, made classical by Darwin's experiments, was extinct. This is not so—a cock won the first prize in the "any other variety" class, at the last Crystal Palace Poultry Show—but it is now very rare. Thus it seems to me worth mentioning that its characteristic points have undergone a great additional development since Darwin's time. The ear-lobes were then already large, fully continuous with the similar white skin of the face, and confluent with the throat-skin behind the wattles, but they did not hang down so far as those. By the 'seventies they did so, in some specimens at any rate, but still retained their character as ear-lobes. This has now been entirely lost; they form but the lateral portions of a great white bib or horizontal dewlap, which extends an inch or two below the wattles, the throat-skin having been much developed in the downward direction also.

It is obvious that this alteration must have been effected by selection within the breed, as no outcross could have been used, no other breed having the white face. Thus we have here one structure definitely changed into another by selection of small variations in about half a century. The cock above mentioned is figured in *Poultry* for Dec. 30, 1927.

A New 18-inch Cœlostat.

For investigations of the sun it is usual to employ spectrographs of considerable weight and length, which it would obviously be impracticable to mount on an equatorial telescope. The plan generally adopted is to place the apparatus in a room where it can be firmly fixed and kept at a constant temperature, and to direct the solar image into it by means of a mirror.

Various instruments have been devised for reflecting the light from a celestial object in a given direction, such as the siderostat and the Foucault and Stoney heliostats, which are arranged to give a double motion to a plane mirror. These all suffer from the defect that they rotate the image and are therefore not suitable for solar work.

The cœlostat is, however, free from these defects. It consists simply of a plane mirror in a metal cell to which are fixed two pivots or trunnions at opposite sides and exactly in line with each other, so that the mirror is rotatable about an axis parallel to its upper plane silvered surface. This axis has to be set truly parallel to the earth's axis, and the mirror is rotated by clockwork at the rate of once in 48 hours in a direction opposite to that of the earth's rotation. If then we look at a star reflected in the mirror, the image will appear to stand still, because the forward motion of the star is exactly counteracted by the backward motion of the mirror, remembering that the reflected ray always turns at twice the angular speed of the mirror. In order that the light can be sent in a convenient direction (usually either vertical or horizontal), it is necessary to place a second mirror in its path.

The following account is a description of a large instrument of this type with an 18-inch plane mirror, which has recently been made for the Commonwealth Solar Observatory at Canberra, New South Wales, by Sir Howard Grubb, Parsons and Co., of Newcastle-on-Tyne.

This cœlostat possesses a number of interesting features. For example, the mirror is made of Pyrex glass, and the driving clock is perpetually wound by a small electric motor. Both the quick and slow motions to the mirror are operated electrically from a distance by suitable magnets and a reversible motor. The complete apparatus weighs 480 lb. It will be mounted with its second mirror of 18 inches aperture on a rotatable carriage at the top of a building, and the beam will pass vertically downwards through a 12-inch objective and thence will be reflected by a 10-inch mirror into a horizontal spectrograph.

A complete cœlostat, therefore, will consist of a mirror mounted in bearings, with some arrangement by which the inclination of its axis to the horizon can be set exactly equal to the latitude of the observatory. There will also be a clock, similar to the driving clock of an equatorial telescope, which may, or may not, be on the same base. It is more compact if all the parts are mounted together, but the vibration of a clock, especially if electrically wound, is often difficult to overcome. It must be possible to increase or reduce the angular speed of the mirror from a distance by a very small amount for guiding while taking a photograph; and means must also be provided for moving the mirror quickly when making the preliminary rough setting. In the present instrument the quick setting is performed by a small motor with an auxiliary worm and wormwheel, mounted on the mirror spindle and rotating with it; thus the rough adjustment can be very conveniently performed by the operator from the slit end of the spectrograph.

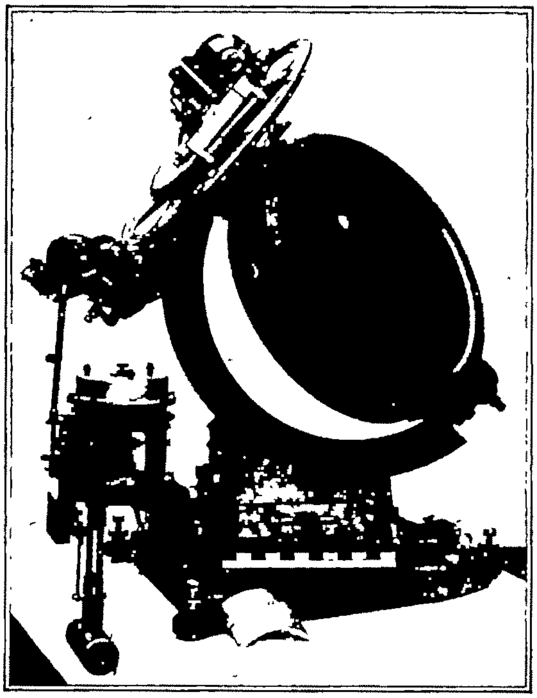

Fig. 1.—View of cœlostat from east side.

The Mirror.

The mirror is 18¾ inches in diameter and 3 inches thick, weighing about 72 lb., and silvered on the optically worked upper surface. The material chosen was Pyrex glass, made by the Corning Glass Co. of New York. The advantage of Pyrex over common glass is mainly its low coefficient of expansion. When a cœlostat is used in sunlight, the upper surface expands and forces the whole mirror to adopt a somewhat convex shape, which not only produces a marked change of focus, but also introduces astigmatism into the image. An additional advantage of this glass is found in the polishing process, because the heat generated by the polisher does not produce so much change of shape as is the case with ordinary glass. It is more difficult to grind than hard crown, but takes a very fine polish.

The mirror cell consists of a circular cast-iron box, with about ⅛-inch clearance all round and below the mirror. The glass rests on three brass discs, 4 inches in diameter, mounted by ball and socket on the ends of three levelling screws. This ensures that the mirror will rest rigidly and firmly in the cell. To prevent any lateral movement, the mirror is held by eight equidistant pads about 2 inches square, mounted in pairs on pivoted rockers outside the cell. The two lower rockers, which bear the weight of the mirror disc, are solid and turn on fixed pivots; but the upper rockers consist simply of flat steel springs adjusted by milled screws. After lowering the mirror into place, a gunmetal retaining ring is screwed on the top of the cell and the glass is pushed up into contact with this ring by the three levelling screws. A fourth central screw is also provided which is made sufficiently long to lift the whole mirror right out of the cell for re-silvering.

Massive pivots 1⅝ inch diameter are bolted to this cell at opposite sides in such a way that the axis of rotation lies accurately parallel to the plane of the upper reflecting face of the mirror.

The Mounting.

The mirror pivots pass through gunmetal bearings at the extremities of a heavy semi-circular casting, which is clamped to a cradle on the main case casting. By loosening this clamp, the whole semi-circular frame can be moved round to alter the inclination of the mirror-axis to suit different latitudes. The thrust due to the weight of the mirror is taken by a ball at the lower end of the axis. Provision is made for a small adjustment in azimuth.

The main wormwheel, or driving circle, which is strung on the upper pivot of the mirror box, is a gunmetal casting 19 inches in diameter, and is cut with 720 teeth. It is driven by a steel worm having a period of four minutes. The drive from the clock (one turn in six seconds), is transmitted to the driving screw by bevel and worm gearing through a vertical shaft the length of which can be varied to suit different latitudes. With the clock mounted on the base, and the large wormwheel of the present instrument, the latitude can only be adjusted over a few degrees, but if the clock were mounted independently a range of from 65° N. to 65° S. could be obtained.

The Slow Motions.

Between the clock and the main worm there is inserted an arrangement of gears for providing slow motions to the mirror. The clock shaft rotates once in six seconds, and the vertical shaft rotates at the same speed; after this the system is broken in two places, and at each break is inserted one of Sir Howard Grubb's well-known differential epicyclic gears (Fig. 2). So long as this gear is left free, it will rotate with the shaft and the whole will go round as one unit. By means of an electro-magnet, a small brake can be applied to the disc carrying the planet wheel, and then the clock will turn one of the large gears; this turns the planet about its own spindle, and the planet in its turn drives the other large gear. The numbers of teeth on these gears are 92 and 90; thus on applying the brake an acceleration of about 2 per cent. is obtained. A corresponding deceleration results if the brake is applied to the second (reversed) epicycle. These slow motions are for guiding, on account of the constantly varying refraction of the atmosphere. Pressing a key for three seconds will produce a change in the direction of the reflected ray of 1″.

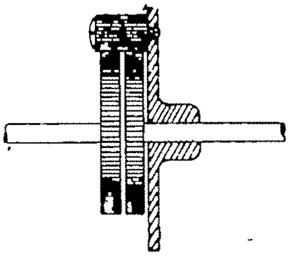

Fig. 2.—Sir Howard Grubb's differential epicyclic gear.

The Clock.

The clock is a distinctly novel arrangement and works extremely well. It is primarily a weight-driven clock with friction governor worked by an endless chain on Huygens' principle, so that the clock may be wound by an electric motor without the necessity of any maintaining power (Fig. 3).

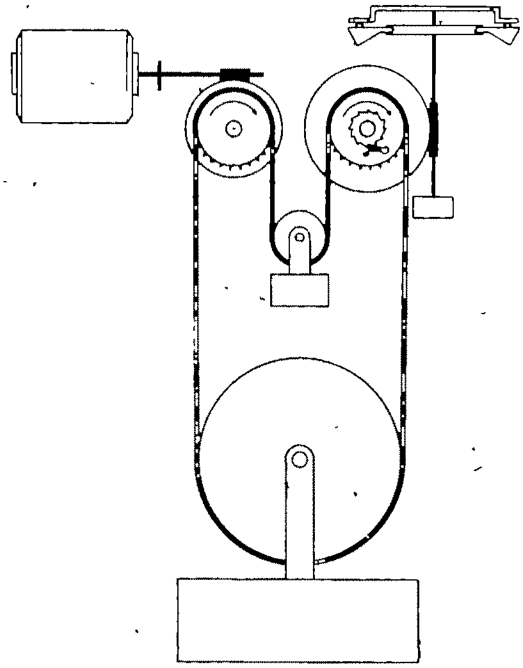

Fig. 3.—General arrangement of the driving clock.

The chain passes over two sprocket wheels, one on the motor winding shaft, and the other on the main clock shaft. On the latter is also a worm-wheel which drives the governor through a reversed worm arrangement. The governor spindle is vertical, and rests on a ball-bearing race to take the thrust of the reversed worm. There are four hinged governor weights which rise up by centrifugal force until the pads on their upper surfaces rub against a brass ring, and the friction then suffices to keep the clock running at a fixed speed. The speed can, however, be altered by an adjusting screw which lowers or raises the whole spindle, and thus allows more or less movement for the governor-weights.

The endless chain also supports two weights, of which the main lower one weighs 11 lb., while the small upper one of ¼ lb. simply serves to keep the chain taut. The up-and-down movement of the main weight operates a small rheostat controlling the speed of the winding motor, so that as the weight rises it introduces more resistance, thus slowing the motor until a balance is obtained. The weight then floats almost stationary, and the motor winds at the same rate as the clock unwinds. A second rheostat is also fitted, so that the motor speed may be approximately adjusted when the instrument is installed.

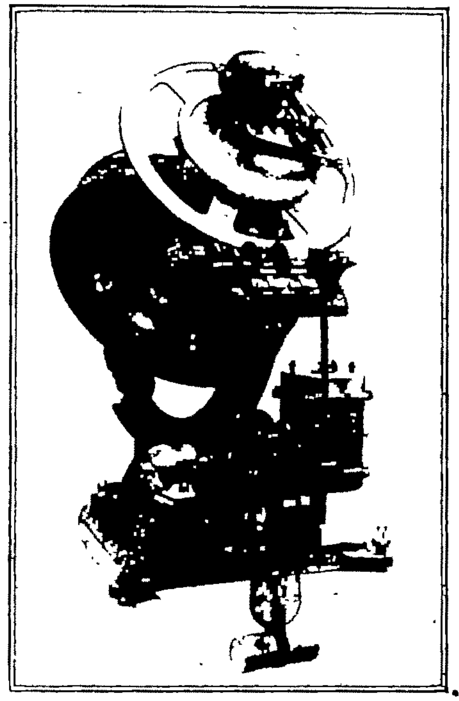

FIG. 4.—Arrangement of clock, gearplate, and driving circle.

When the motor is switched off, the main weight continues to fall and the little weight rises until ultimately it will reach the top of its travel and stop abruptly. In order to prevent damage, due to the great inertia of the governor, a ratchet is incorporated in the clock sprocket to allow the governor to run on freely.

The motor armature was carefully balanced by the makers, and as an extra precaution against vibration, the whole motor is mounted on thick pads of Sorbo rubber and the drive is transmitted through a thin flexible coupling.

To ensure the utmost accuracy in the rate of the mirror, the speed is further controlled by a pendulum, using the 'Russell' type of control. Just before the main spindle leaves the clock, a friction clutch is inserted that will slip if anything obstructs the free movement of the spindle. Round the edge of this clutch is a series of six pins which travel past at the rate of one per second, and a steel pawl is so placed that it catches one of these pins and holds it stationary until the pawl is drawn clear by an electro-magnet operated by a pendulum of an accurate clock. In this way the motion is held momentarily until released by the controlling pendulum at the end of each second. It is, of course, necessary to run the coelostat clock a trifle fast in order that this control should be effective. The arrangement of these various mechanisms is clearly shown in Fig. 4.

THE ELECTRIC QUICK MOTION.

This is a great convenience in setting the mirror from a distance into the correct position at the commencement of observation. To avoid having to unmesh the driving worm, the main wormwheel is loose on the mirror shaft, but the drive is transmitted through a small auxiliary worm and wormwheel which can be turned by an electric motor also mounted on the spindle. In the ordinary way the whole arrangement, including its motor, turns with the mirror once in two days; but when the quick motion is required, this auxiliary motor is started up and the mirror shaft then rotates, independently of the main wormwheel, at the rate of one turn in about two minutes. The motor is, of course, reversible from the distant control switch, and the current is led to it through four slip-rings and wipers. The worm drive for this quick motion can be thrown out of gear when it is desired to turn the mirror by hand.

The Suez Canal in Relation to the Marine Faunas of the Mediterranean and Red Seas.[1]

THE marine faunas of the Mediterranean and Red Seas differed so widely from one another before the opening of the Suez Canal that in many groups, if a species was found in one sea, it was almost certain that it did not occur in the other. Since then there have been a few Red Sea crustaceans found all over the Mediterranean, and a swimming crab is being commercially fished along the North Egyptian coast, where also the Red Sea pearl oyster is common. The intermingling of the two faunas being clearly an object of great interest, the Royal Society provided the requisite funds for the Cambridge Expedition, the first reports of which are now before us. The leader of the expedition was Mr. (now Prof.) H. Munro Fox, who for several summer vacations had worked at the Suez end of the canal, and with him were associated Mr. Robert Gurney, Mr. V. C. Robinson, and Mr. D. N. Twist. Help was also given by the directors of the Orient Line, and the expedition received an unstinted, generous, and most practical welcome from the Suez Canal Company and the Egyptian Government.

Along the line of the Suez Canal are limestones of Cretaceous and early Eocene ages, the arm of the Mediterranean that extended down what is now the Red Sea only coming into existence in the

---

[1] Cambridge Expedition to the Suez Canal, 1924. (London: *Transactions of the Zoological Society*, 1926. Part I.

Miocene, when the whole area was peopled from the Mediterranean. In the Middle Pliocene a connexion was formed that allowed an invasion of Indian Ocean animals. How and when exactly the Isthmus of Suez was built is not known, but in the Pleistocene there was a freshwater lake over part of what is now the Isthmus, this containing a series of molluscs of species many still living in the Upper Nile.

It was at this period that the fauna of the Gulf of Suez assumed its almost completely Indian Ocean facies, and the fact that it did so is remarkable enough and by itself quite sufficient to make desirable the present study. The Bitter Lakes were once an arm of the Red Sea, the top of which periodically was isolated and dried up, giving alternate layers of salt and sand. The Pharaohs dug a canal connecting the Bitter Lakes and so the Gulf of Suez to the Nile, and this continued more or less open until the eighth century. It was not a traffic route, as the terminal ports were in Egypt itself, and so differs scientifically from the present canal, the connexion being through a long stretch of fresh water, without unbroken journeys by means of which animals attached to ships could pass from one to another area.

The scientific results of the expedition can only appear gradually as groups of animals are worked out. The Bitter Lakes have increased in depth by nearly three metres, owing to salt solution, since the canal was opened, but the maximum density of their surface waters is only 1037—bottom 1042 = salinity 1·053—as compared with average densities of about 1027 and 1031 in the Port Said and Suez Roads respectively. At Lake Timsah the density varies from 1006 to 1036, and in places fresh water overlies the sea water, each containing its own organisms. The fauna and flora of the canal are poor, probably due to dredging and the churning up of the water by ships, since piles and mooring buoys show abundant growths. The bottom of the Bitter Lakes is covered, over the salt bed, by black mud devoid of macroscopic life, but the shore regions show a fauna and flora richer in numbers of species and individuals than similar areas at either end of the canal. Rather unexpectedly, there is no sign of stunting or deformity except in the Foraminifera, some organisms showing markedly increased size.

Clearly, to-day salinity is no barrier to migration, to the swimming, crawling, or carrying of adult organisms between our seas, but it may have been in the past, since the density of the Bitter Lakes in 1869 was 1123,—and it may still be to forms only distributable by delicate larvæ or eggs peculiarly subject to changes of osmotic pressure. The amount of hindrance by reason of high temperatures is small, but more data are required. Tugs, coal barges, etc., dirtied by organic growth, are frequently changed over from the terminal ports and are helpful. Currents deduced by Prof. Fox from density observations show that Bitter Lake water, as affected by Red Sea tides, is carried from October to July nearly to Port Said, and Mediterranean water to beyond Lake Timsah in August and September. Of 12 groups of organisms there are found in the Canal 83 Mediterranean and 234 Red Sea species, but we must await further lists and analyse these into areas, while the breeding dates are all important in respect to currents.

Scientifically, periodic investigations of the Suez Canal flora and fauna should have been made in the past in respect to which there are no data such as are now required. The expedition under discussion has collected all there were and given a definite basis upon which future science can work. It cannot, however, be deemed to have completed its task until its members pay a further visit to the canal to study the conditions from July to September, the months of heat and of northerly currents, one member in advance to collect data on breeding in the previous quarter.

Obituary.

PROF. J. FIBIGER.

IT is a tribute to the perennial fascination of the cancer problem that Johannes Fibiger, whose sudden and unexpected death on Jan. 30, at the age of sixty years, is deplored by the medical profession of the world, only became known to the wider medical and lay public through his contribution to its solution. It is eloquent of the importance and value of his work that his death has evoked world-wide tributes to his memory.

Fibiger was appointed professor of pathology in the University of Copenhagen in 1900, and until 1913 was known only to pathologists through his careful work on tuberculosis. In 1913 the accidental discovery of cancer of the stomach in rats associated with the presence of nematode worms in the actual substance of the growth, started him on the intricate and arduous investigation which led to the discovery of the first successful method of experimental cancer production. The magnitude of this achievement is seen in the great expansion to which it has led, in the study of neoplastic growth. The tar cancer work of Yamagiwa, Itchikawa, and Tsutsui was directly inspired by it, and Fibiger himself was quick to discern the experimental advantages of the chemical method, his own researches in the subject doing much to establish it in the forefront of the means at our disposal for probing the caustive factors in malignant disease. Even more directly the offspring of Fibiger's genial discovery, is the method of sarcoma induction in the liver of the rat by the larvæ of *Tænia crassicollis*, worked out by Bullock and Curtiss. The production in animals of X-ray, paraffin, and arsenic cancer easily followed as an extension of the avenues of attack opened by Fibiger.

The substitution of exact experiment in the place of more or less nebulous speculation, to which the discussion of cancer etiology was previously restricted, is now acknowledged by all serious students of the cancer problem as the most precious and enduring consequence of Fibiger's discoveries. Their permanent value will inscribe his name beside that of Virchow, on whose theory of chronic irritation it has placed the crown of experimental verification.

The recent award to him of the Nobel Prize in Medicine was welcomed by Fibiger's friends and admirers throughout the world. In 1926 he was made Rector of his University, a post which he filled with dignity and distinction. His unfailing personal courtesy and energy were proof even against the tedium of international conventions, and in his addresses, as in his published work, he combined brilliance with accuracy, sanity and restraint with enthusiasm. J. A. Murray.

Mr. J. E. Harting.

Mr. James Edmund Harting, who died on Jan. 16, was the son of a Roman Catholic solicitor and was born in 1844 in Chelsea. He was educated at Downside College and, after taking his B.A. at the University of London, he joined his father's firm and practised for some years as a solicitor. Always attracted to natural history, he continued his observations of Nature, more especially of bird-life, in and around London, and one of his earliest papers, "A list of Waders that have appeared at Kingsbury Reservoir in 1863," appeared in the *Zoologist* for that year. From this time onwards, Nature articles from his pen appeared regularly in the *Field*, the *Sussex Zoologist*, the *Middlesex Zoologist*, and in many other journals, but the great majority were written for the *Zoologist*, and in 1877 he became the editor of this journal, a position he retained until 1896. From 1871 he was naturalist editor of the *Field*, and later shooting editor also. On the opening of the Natural History Museum at South Kensington he was appointed to form the zoological library, and the zeal and energy with which he worked is attested by the magnificent collection of books now in the Museum available for reference.

Among the more important of the many books written by Harting were "The Birds of Middlesex" (1866); "The Ornithology of Shakespeare" (1871); "A Handbook of British Birds" (1872), of which he brought out a new and revised edition in 1901; in 1875 he edited an edition of White's "Natural History of Selborne"; "British Extinct Animals" (1880); "The Birds of Hampstead" (1889); and "Bibliotheca Accipitraria" (1891), this last being perhaps the most valuable of all his works. In addition, however, to the above-mentioned works of a more or less scientific character, he wrote many books indirectly connected with ornithology, such as "Ostriches and Ostrich Farming" (1879) and "British Game Birds and Game Laws" (1912).

As a writer, Harting had the knack of making his subjects interesting even when they appealed only to a small circle of readers, whilst his popular and semi-popular books and articles showed a wealth of knowledge and accurate observation of Nature, recorded with a charm that disarmed even those who disagreed with his deductions. From a scientific point of view, Harting was, unfortunately, so conservative that modern methods annoyed and irritated him. In consequence, he often refused to accept facts which, in his heart of hearts, he knew to be true, or arguments which he knew to be irrefutable. Nevertheless, his recent death leaves the scientific world the poorer, whilst the Nature-lover loses a writer who, whatever he wrote, was always well worth reading.

Mr. George Muirhead, successively factor on large estates in Berwickshire and on the Earl of Aberdeen's properties in Aberdeenshire, and for the last quarter of a century Commissioner on the Scottish estates of the Duke of Richmond and Gordon, had exceptional opportunities for studying the natural history of Scotland in very diverse regions. He made the most of these, and for long had been well known throughout the country on account of the particular interest he showed in bird life, in the artificial rearing of salmon and trout, and in floriculture. More than twenty years ago Mr. Muirhead conducted a series of experiments on the rearing of salmon fry in salt-water ponds near the estuary of the Spey, and succeeded in rearing fry, received from the hatcheries at Gordon Castle, through the smolt to the grilse stage. His most important work was his "Birds of Berwickshire," the two volumes of which, published in 1889 and 1895, comprise much more than the ordinary local fauna, since they include readable accounts of the past history and of the legendary lore of the species found in the county. A few years ago the University of Aberdeen recognised the merit of his work by granting him the degree of LL.D. He died on Jan. 29 at the ripe age of eighty-two years, and is survived by his widow, the eldest daughter of the late Lord Sempill.

We regret to announce the following deaths:

Prof. P. Carmody, Director of Agriculture and Government Analyst, Trinidad, on Feb. 10, aged seventy-one years.

Dr. R. S. Holway, emeritus professor of physical geography at the University of California, on Dec. 2, aged seventy years.

Dr. W. L. Johannsen, professor of plant physiology in the University of Copenhagen and a foreign member of the Swedish and of the Austrian Academies of Sciences, on Nov. 11.

Mr. Richard Kearton, author of several popular books on natural history, and associated with his brother, Mr. Cherry Kearton, in the kinematography of wild animals, on Feb. 8, aged sixty-six years.

Colonel J. P. Koch, Chief of the Danish Military Air Service, who had taken part in many exploring expeditions in Greenland, on Jan. 13.

Prof. Otto Krug, Director of the Agricultural Experimental Station and Public Institute for the Examination of Foodstuffs at Speyer, on Dec. 25, aged sixty-four years.

Prof. Ludwig Milch, Director of the Institute of Mineralogy and Petrology at the University of Breslau, on Jan. 5, aged sixty years.

The Right Hon. the Earl of Oxford and Asquith, F.R.S., on Feb. 15, aged seventy-five years.

News and Views.

The funeral of Prof. H. A. Lorentz, which took place at Haarlem on Thursday, Feb. 10, afforded a striking tribute to the honour and esteem in which he was held by all sections of his countrymen. Representatives of the King and Queen, the Government, and municipalities were present, and the funeral procession passed through the streets of Haarlem along a special route, which was lined with people. Not only were the universities and scientific institutions of Holland strongly represented, but there were also representatives of foreign academies, including Prof. P. Langevin, Mme. Curie, Prof. A. Einstein, Prof. J. Verschaffelt, and Sir Ernest Rutherford, the latter representing the Royal Society of London. An eloquent eulogium on Prof. Lorentz was delivered at the graveside by Prof. Ehrenfest, successor of Prof. Lorentz in the chair of theoretical physics in the University of Leyden, and was followed by short addresses by Sir Ernest Rutherford, Prof. Langevin and Prof. Einstein. In these speeches, emphasis was laid not only on the magnitude of his contributions to science both by his teaching and investigations, but also on his fine personality and character and the strong influence for good he had exerted in international scientific affairs.

Consternation has been aroused by the proposal to build a beet-sugar factory on the banks of the River Wye near Hereford, which would discharge several million gallons of putrescible effluent daily into this fine and valuable salmon river during the sugar season. Judging by the disastrous effect which this effluent has had upon other rivers, the anxiety is well justified, for they have been depleted of oxygen and coated with sewage fungus for many miles below the point of discharge. While the provision of factories and employment can only be viewed with satisfaction, particularly by the Minister of Agriculture and Fisheries in his former capacity, the pollution of one of our finest and most beautiful salmon rivers can only be viewed with dismay, particularly by the Minister of Agriculture and Fisheries in his latter capacity. Up to the present time it has been found impracticable to render the effluent non-putrescible at a reasonable cost owing to its large volume. Research concerning possible methods of treatment has been recently inaugurated under the auspices of the Department of Scientific and Industrial Research, and is, we understand, in active progress at Rothamstead. Upon the successful issue of these investigations, rendered difficult since the cost of treatment must be small, rests the possibility of working sugar factories on clear rivers, such as the Wye, without destroying not only the fishing but also, and to a marked extent, the amenities of the riverside. In common with all who desire both increased employment and the preservation of our rivers, as such and not as sewers, we wish good hunting to the small band of workers who are attacking this problem.

In 1926 a copy of Barrow's "Euclidis Elementorum libri XV." (1655) was sold by auction for five shillings. It proved to be Newton's own copy and to be full of his notes. In the Newton memorial volume, prepared under the auspices of the Mathematical Association and published last year (Bell and Sons, Ltd.), the conjecture was hazarded (p. 170) that this was the only relic left of Newton's Cambridge library of at least 2000 volumes. Now comes the startling news that Col. de Villamil has unearthed from a private house in Gloucestershire, where they have been lying for the last two centuries, at least a third of the missing volumes, and that they include some of the books from which Newton must have reaped his early acquaintance with the subject he was to adorn. A short account of the find is given in the *Morning Post* for Feb. 8. The treasure trove includes classical texts, works on alchemy and the chemistry of the day, and on religious topics. Many of them are autograph presentation copies, contain his own signature, and show by copious annotations every sign of having been closely studied.

Among the mathematical works which Col. de Villamil has found are Newton's own copy of the "Principia," corrected in preparation for the second edition, to be edited by Roger Cotes; the "English Euclid" mentioned in Brewster's "Life" (i. p. 22), probably Barrow's edition of 1660; Seth Ward's "Idea Trigonometriæ demonstratæ (in usum juventutis Oxoniensis") (1654); Norwood's "Trigonometrie, or the Doctrine of Triangles" (8th edition, 1685); and what is described as Descartes' "Philosophy." Another interesting item is Newton's own Greek-Latin lexicon (1650). bought, according to the fly-leaf, on Mar. 26, 1661, for sixpence. Some of the books belonged to Barrow, *e.g.* his Greek Testament (1653), and his presentation copy of Stillingfleet's "Discourse on Idolatry," etc. A further and detailed account of the contents of this unexpected—or should we say, long-expected—find will be awaited with impatience. Meanwhile Col. de Villamil, who is old enough to have learned his Euclid from Oliver Byrne's coloured diagrams, must be warmly congratulated on the good fortune which has brought in his way so striking a discovery.

A merry combat has been raging around the subject of evolution since Sir Arthur Keith restated the case at the Leeds meeting of the British Association. Trumpets which have lain silent for years are blazing forth challenges to science, and weapons old and rusty with disuse are being burnished for the fray. We are not surprised, knowing something of the strength of fundamentalist feeling which lay dormant in Great Britain, hoping and waiting for the gradual overthrow of Darwinism. But what is surprising is the progress which the doctrine of evolution has made in the meantime even in the quarters which now challenge the sequel. Take the article on "Truth and Error in the Doctrine of Evolution" by Dr. J. A. Fleming, in the January issue of the *Nineteenth Century*. Dr. Fleming is a distinguished electrical engineer and, as a matter of course, knows a great deal about recent developments in physical science. He is prepared, therefore, to accept the findings of the astronomers and physicists, and admits the evolutionary development of, say, the solar system. But he clearly knows a great deal less about the discoveries of biological science, and, perhaps as a consequence, is not prepared to accept the findings of the biologists. Yet when he reaches the greatest stumbling-block of all, the position of man, even he admits that "as regards bodily structure [the human race] is unquestionably closely allied to the animal races, and especially to the higher mammalia." His main difficulty in accepting evolution lies in the high qualities of man, which seem to cut him off as a being apart from the animal world, but here his misstatement of the facts is patent. All the existing races of mankind he regards as possessing the *same* marvellous qualities. Gradings, essential to the evolutionary view, are ignored, and the lowly Fuegans are (presumably) bracketed with the highest Caucasians. Had the author followed the course which he himself proposes, of endeavouring to trace the characteristics of finished humanity backwards to their simpler manifestations, he would have found a diminishing series through the Iron and Bronze Ages, to the neolithic and various palæolithic stages, which might have suggested that the series did not end there.

THESE are not the points to which Sir Arthur Keith has given prominence in his rejoinder, "Evolution and its Modern Critics" in the February issue of the *Nineteenth Century*. Both Dr. Fleming and another critic, Mr. G. H. Bonner, argue that the intelligent perception of orderliness and plan in Nature implies an intelligent planner. It is the old story of Paley's argument from design, the watch and the watchmaker, the contrivance which could not exist without a contriver; an argument which, seemingly invincible, "was yet in less than a generation replaced in classrooms, laboratories, and learned societies by that of Darwin." Paley forgot that even his watch had an evolution, and Darwin's argument succeeded because "he produced such a prodigious number of facts which could not be explained if special and instant creation was true, but which fell into place and assumed a rational order if the doctrine of evolution were valid in the world of living things." The human thighbone shows as clear evidence of architectural skill as Paley's watch, yet the internal struts carrying just the proper strains in the proper places are built by cells acting in response to the physical forces which play upon them. Architect and mason are one. "There is no duality of function in living matter." The critics are loth to surrender the uniqueness of the human 'soul': they say, a man is not his body; it is the soul, manifesting in a physical body in order to unfold, that is man. But the intricate manifestation "as we medical men know it, depends solely upon the brain"; the human soul is "the inward response and outward manifestation which is given by every living human brain."

THE Lewis Evans Collection at Oxford has recently received several very valuable gifts. One of these, the great silver microscope of George III., has already been referred to in our columns (Feb. 11, p. 226). Now the great Companies of the City of London have materially increased the fund for the collection, originally started with £1000 from the Goldsmiths' Company, on condition that the University devote to the collection the necessary accommodation in the Old Ashmolean Museum, and make such other arrangements for its future maintenance, care, and display as will enable the gift to be secured to Oxford, and available for study. In making these additions to the Lewis Evans Fund the subscribing Companies were greatly influenced by the very close relationship between the ancient museum of John Tradescant in Lambeth and the Old Ashmolean at Oxford. Both were science museums. Ashmole's museum was the child of *Museum Tradescantianum*, with a rich share of the parental qualities, and a richer endowment of the family heirlooms. Until the recent revival of the old Museum its scientific origin was forgotten, being obscured by the growth of the art and archæological side, while the original scientific treasures of the seventeenth century were relegated to the cellars of the University. Yet, as has been aptly said, "Tradescant's Museum was for the London of the 17th century what the British Museum plus the Imperial Institute plus Kew is for London of the 20th century."

THE Old Ashmolean was opened in 1683, wholly as a scientific institution. At present one-third only is available for scientific purposes, for its original laboratories are being used for the storage of Bodleian books, while a second third is used for completing Dr. Murray's "New English Dictionary." The plans for a great extension (or a great reduction) of the University Library give ground for hope that accommodation for both books and the dictionary staff may be found elsewhere than in a building which is now the oldest building in Britain that was specially built for the study and teaching of natural science. Contributions to the endowment fund, such as those from the City Companies, for which the University has recently recorded a decree of thanks, will materially aid objects which have the sympathy of all interested in the history of science in Great Britain.

THE announcement in the *Times* of Jan. 9 that Dr. Hans Merensky had found artesian water in the gneiss formation of Namaqualand is important, if borne out by experience. The vegetation of this region is mostly fed by the sea-mists that drift in, and is singularly beautiful. At dawn the rolling downs in the Sand Veld become white, yellow or blue in patches acres in extent, as the sun touches the buds of the flowers interspersed among the grass; while in the Harde Veld, where the rock appears at the surface, the Mesembrianthemums afford a rich pasture for sheep. The curse of the country, however, is the want of water, so that the whole region lies idle until the rare showers fill the water-holes and valleys. The recent discovery of diamond gravels along the coast has made the finding of water imperative, as it would be useless for the Government to proclaim the fields open for prospecting if there is no water for the people who would flock in, in the hope of making their fortunes.

The Namaqualand gneiss is banded, with occasional slips of schist, which are metamorphosed sediments caught in the folds. It is a possible theory that the gneiss itself is the mashed-up sediments that have become entirely altered under extreme metamorphism. In the rock-shaft at the Kimberley Mine at 2520 ft. there were the ordinary shales and grits; at 3520 ft. the schists were riddled with a network of dykes of pegmatite; it was hoped to see the transition into a continuous mass of gneiss at the next level, but unfortunately the Blue Ground came to the end, and it was never cut. If this has been the history of the vast area of gneiss as a whole, it is quite conceivable that certain beds were more resistant to metamorphism, such as bands of quartzite, which, in the folding, would form impervious layers, and so help to constitute artesian basins in which subterranean water could be stored.

We are reminded in the seventh annual report of the (British) Electrical (and Allied Industries) Research Association, known as E.R.A., that the problem before Great Britain is to provide a means which will enable its population of nearly fifty million persons to live and prosper. For about four-fifths of their food and for a large fraction of the raw materials of industry, the inhabitants of these islands depend on supplies from overseas. These supplies can only be obtained if the manufacturing industries in the country are able to carry on export trade in future with greater efficiency than the rest of the world. This is not done by lowering wages or increasing working hours. Commercial skill and organisation alone cannot succeed. It can only be done by research. Every stage in the production of the finished article must be done as efficiently as possible. Physical researches of the greatest difficulty have continually to be made, and these make the greatest demands on our physical knowledge and our manual skill. It has been found necessary to modify some of the conclusions previously arrived at. The method of finding the temperature rise in buried electric cables needs modification; this is probably due to the fact that the thermal properties of the soil round the cable are not accurately known, and this subject is being investigated. Special attention is being given to high voltage and high frequency work, and satisfactory progress is being made. The researches conducted by Prof. Callender on the properties of steam have been most successful. They are not only of importance in connexion with the design of steam turbines and boilers, but are also of value to the scientific worker. The expenditure of E.R.A. has now been extended from £16,000 per annum to £24,000 per annum, and the Association looks forward confidently to manufacturers and electric supply companies for support. Sir John F. C. Snell, chairman of the Electricity Commission, has been elected president for the ensuing year.

Sir William Bragg delivered a further lecture "From Faraday's Notebooks" at the Royal Institution on Feb. 9. When water lies in a pool on a vibrating support, quivering motions often appear on its surface; and sometimes the extreme regularity of their arrangement produces an exceedingly beautiful effect. Faraday carried out a number of experiments on these 'crispations,' as he called them. They are found on the surface of the water in a finger bowl when the wet finger is rubbed round the edge; or, as Faraday observed, in the small quantities of rain-water that may lie on the objects in a cart which is rattling over the pavement. Their explanation brings in some interesting points of physical science, for their form depends on the properties of the liquid on which they occur, and they have been used as the basis of a method for measuring liquid surface-tensions. Faraday also observed, when on a visit to Hastings, the curious ridges that form on the water lying in thin layers on the wet sand when the wind blows over the beach, and he pointed out that the ridges are parallel to the direction of the wind; that is, at right angles to the ripples that a wind produces in the ordinary way. These, too, he tried to explain on the same principles that he applied to his crispations. He thought that he saw a similar effect in the ridges that appear upon a water surface when the end of a vibrating iron bar is just dipped into the water; the ridges radiate outwards in approximately straight lines from the end of the bar. Curiously enough, he tried to use this effect as an analogy which would help him to understand how a vibrating body in the ether would cause the emission of rays of light. He proved that the water ridges are due to oscillations of the water at right angles to the ridges, and suggested that there was a similarity to the transverse vibrations which Fresnel had considered to be characteristic of the propagation of light.

The Post Office is to be congratulated on the completion of the long-deferred underground electric railway in London for the conveyance of letters and parcels. It will appreciably contribute to the reduction of surface street traffic. The tube connects the Paddington District Post Office with the Eastern District Post Office. The total length of the railway as at present constructed is 6½ miles. It is the first permanent 2-foot-gauge railway in Great Britain. The minimum diameter of the tunnel between the stations is seven feet, and it accommodates a single track. The operation of the driverless trains is entirely automatic. When a train is standing at a platform ready to be loaded an operator inserts a plug, and a panel which describes where the train is going is illuminated. When the train has been loaded, the foreman operates a switch which lights a green light in the control cabin and a red light on the platform indicator. The switchman then pulls the lever appropriate to the route, starting the train and extinguishing the other lights. The electrical power required for the trains is purchased from two London supply companies and is supplied at 11,000 volts three-phase. It is then converted down in two operations to 440 volts direct current. A train passing through a station does not require to be watched by the switchman, as he can always see its exact position by looking at the illuminated diagram in the control cabin of the station. The trains consist of two or three steel motor wagons, each of which is capable of carrying half a ton. It is possible to dispatch a second train from one station before the arrival of the first train at the next station.

ON Thursday morning, Feb. 9, Mr. Baird succeeded in sending from his laboratory the first glimmerings of images of persons in London to a room in a suburb of New York. The transmission was sent by a telephone wire from London to the radio transmitter at Purley, and from there was broadcast to New York. The waves that produced the pictures were detected by the loud irregular humming noise they produced in a telephone. The pattern of a man's head moving in a human way was clearly seen, but it sometimes faded away. This fading was attributed to interference from short-wave stations in Paris and Mexico City. A picture of a woman's head moving in a natural way was also transmitted. The receiving apparatus used in this experiment was a comparatively simple device. It comprised only a system of rotating shutters controlled by a small electric motor, the source of light being a discharge tube. Mr. Baird attributes the imperfections of the images to atmospherics and fading, and says that they could have been very considerably improved by using a higher-powered transmitter at Purley. The experiment proves that the trans-Atlantic transmission of living pictures is possible, and it indicates some of the difficulties that have to be overcome.

SIDKY PASHA's proposal to the Chamber in Cairo that all royal mummies at present being exhibited in the Cairo Museum or elsewhere in Egypt should be returned to their tombs and reinterred in their sarcophagi, will no doubt commend itself to a certain section of Egyptian opinion for reasons which, perhaps, need not be too closely examined. His views, as explained to the *Times* correspondent and published in the issue of Feb. 8, are from certain points of view unexceptionable, if not entirely convincing. The analogy he draws from the fact that great men of more modern periods are not exposed to view though they were of less importance than the Pharaohs in their day, is somewhat irrelevant. In arguing that scientific requirements alone could justify the continued exposure of the bodies, and that these have long been satisfied, Sidky Pasha assumes that further discovery is no longer possible to future generations of anatomists and archæologists—an assumption as great as the statement that those who now look at these mummies in the Museum are inspired by nothing but a vulgar curiosity. If this were true, it would involve sad implications for those who seek to popularise our museums. The appeal to sentiment in the argument that this is an attempt to comply with the religious ideas of the ancient Egyptians and to meet the requirements of the dignity of Egypt, will add weight to a proposal which it might be difficult to take seriously if it were not a real danger to the future study of ancient Egypt, and if it had not already been applied in the case of Tutankhamen.

PRINCIPAL A. P. LAURIE, of the Heriot-Watt College, Edinburgh, and professor of chemistry at the Royal Academy of Arts, and Mr. Noel Heaton, have been elected honorary associates of the Royal Institute of British Architects.

IT is announced in *Chemistry and Industry* that the Perkin medal for 1927 has been presented to Dr. Irving Langmuir, assistant director of the research laboratory of the General Electric Company, Schenectady. The medal is awarded each year by the American Section of the Society of Chemical Industry to the chemist who, in the opinion of a committee representing the Section, the American Chemical Society, the Société de Chimie Industrielle, and the American Electrochemical Society, has rendered the greatest service to American chemistry.

THE following officers and new members of Council of the Royal Astronomical Society have been elected: *President:* Rev. T. E. R. Phillips; *Vice-Presidents:* Prof. A. S. Eddington, Prof. Alfred Fowler, Dr. J. W. L. Glaisher, Lieut.-Col. F. J. M. Stratton; *Treasurer:* Dr. E. B. Knobel; *Secretaries:* Dr. John Jackson, Dr. H. Knox-Shaw; *Foreign Secretary:* Prof. H. H. Turner; *New Members of Council:* Prof. S. Chapman, Sir Frank Dyson, Mr. W. M. H. Greaves, Dr. Gerald Merton, Prof. E. A. Milne.

AT the recent annual meeting of the Botanical Society of America, the following were elected corresponding members: Abbé G. Bresadola; Prof. S. Ikeno, professor of botany in the Imperial University, Tokyo; Prof. C. H. Ostenfeld, formerly Keeper of the Botanical Museum, Copenhagen; Prof. O. Rosenberg, professor of botany in the Hogskola, Stockholm; Prof. R. von Wettstein, director of the Botanical Garden and Botanical Institute, Vienna. Officers of the Society were elected as follows: President, Prof. A. H. Reginald Buller, of the University of Manitoba; Vice-President, Prof. Irving W. Bailey, of Harvard University.

DR. J. PHILLIPS, whose important botanical work in connexion with the indigenous forest trees of South Africa, carried out at the Knysna Forest Research Station in South Africa, has been referred to from time to time in our columns, has accepted an appointment in the new Research Station to be inaugurated in Tanganyika. It is much to be hoped that the South African Government will find it possible to carry on the important and interesting work to which Dr. Phillips devoted so much energy and perseverance, and which is so fraught with interesting possibilities whilst being of considerable importance to the Forestry Department.

AN American expedition to Nicholas Land, north of Cape Chelyuskin, is announced in a *Daily Science News Bulletin*, issued by Science Service, Washington. This is the Arctic land discovered in 1913 by Com. B. A. Vilkitski and partially explored by him in the following year. Since then it has apparently not been visited. The expedition is to sail in the *Morrissey* under Capt. R. A. Bartlett, and will be mainly concerned with the collection of material for the American Museum of Natural History. No indication is so far given of the date of sailing or the route to be taken.

The title of the *Amateur Aquarist and Reptilian Review* is being changed to the *Aquarist and Pond Keeper*, for it is intended that, besides the usual inhabitants of aquaria and ponds, the journal shall also deal with the mammals and birds which affect these directly or indirectly, either as enemies or friends. The present number (Winter 1927), the last of the old series, includes many short articles of interest to aquarium owners. These are chiefly about fishes, but there are also notes on miscellaneous subjects, such as lizards, snails, and fresh-water plants.

Applications are invited for the following appointments, on or before the dates mentioned:—A part-time demonstrator in chemistry at Birkbeck College—The Secretary, Birkbeck College, Breams Buildings, Fetter Lane, E.C.4 (Feb. 21). A technical assistant in the Department of Fisheries, Irish Free State—The Secretary, Civil Service Commission, 33 St. Stephen's Green, Dublin, C.2 (Feb. 24). A mycologist to the Department of Agriculture, Tasmania—The Agent-General for Tasmania, Australia House, Strand, W.C.2 (Feb. 29). A woman staff lecturer and demonstrator in the Department of Physics of Royal Holloway College—The Principal, Royal Holloway College, Englefield Green, Surrey (Mar. 14). A professor of biochemistry at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, South Kensington, S.W.7 (April 12). Male cartographers in the Hydrographic Department of the Admiralty—The Secretary, Civil Service Commission, Burlington Gardens, W.1 (return of application forms, May 24). A research worker with metallurgical training, in the Research Laboratories of the General Electric Company, Ltd.—The Director, Research Laboratories, G. E. Company, Ltd., Wembley. A junior veterinary surgeon in the Department of Agriculture, Southern Rhodesia—The Secretary, High Commissioner for Southern Rhodesia, Crown House, Aldwych, W.C.2. A director of agricultural research and of experiments and demonstrations in the application of fertilisers, and a director of fertilised propaganda, under the Chilean Nitrate Committee—The Chilean Nitrate Committee, Friars House, New Broad Street, E.C.2. A head of the Department of Biology of Huddersfield Technical College—The Director of Education, Education Offices, Huddersfield.

Our Astronomical Column.

Fixing the Date of Easter.—A new Bill, entitled the Stabilisation of Easter Bill, 1928, is being introduced as a private member's bill in the House of Commons by Capt. Bourne and is down for a second reading on Feb. 17. The Bill, which is to regulate the date of Easter Day and other days depending thereon, provides that "Easter-day shall, in the calendar year next but one after the commencement of this Act and in all subsequent years, be the first Sunday after the second Saturday in April."

The Total Eclipse of August 31, 1932.—This is the only total eclipse in the next eight years that is visible in an easily accessible region. A recent *Daily Science News Bulletin*, issued by Science Service, Washington, gives the particulars about it that have been calculated by Dr. L. J. Comrie of the *Nautical Almanac* Office. The eclipse is total in eastern Canada and the north-eastern corner of the United States; it occurs at 3.30 p.m., height of sun 30°, duration of totality 100 seconds, width of totality track 100 miles; the central line runs from Pierreville, Quebec, to Biddeford, Maine. The southern limit of totality runs from Montreal to Salem, Mass.; the northern limit from St. Jean des Chaillons, Quebec, to Richmond, Maine. The central line passes over the White Mountains. Three Rivers and Sherbrooke in Quebec, Portland in Maine, and Portsmouth in New Hampshire are all suggested as suitable stations. Montreal is too near the edge of the track, except perhaps for some investigations of a special character. Boston is very close to the track, but just outside it. It will be remembered what enthusiasm was excited in America by the eclipse of January 1925. That of 1932 crosses a region not much less populous; it comes at a better time of the year and the sun is higher, so still more successful results may be hoped for.

This is a return after two Saroses of the eclipse of 1896, Norway, Novaya Zemlya, Japan; and after one Saros of that of 1914 (Sweden and Russia); the eclipse is nearing its end in the Saros cycle, and 1932 is the last occasion on which it will be visible under favourable conditions in accessible regions.

The Sun's Rotation and the Relativity Shift of Spectral Lines.—A paper by Mr. J. Evershed dealing with "The Solar Rotation and the Einstein Displacement derived from Measures of the *H* and *K* Lines in Prominences" is published in *Mon. Not. Roy. Ast. Soc.*, Dec. 1927. It is well known that, at the photospheric level of sunspots, the sun's angular rate of rotation diminishes from the equator towards each pole. Spectroscopic observations of the Doppler effect made by Adams in 1908 indicated that the angular speed of rotation also increases from the photosphere outwards through the chromosphere. In 1925, Evershed published his results obtained from spectroscopic observations of prominences, which gave the unexpected value at the sun's equator of nearly 17° for the daily sidereal rotation as compared with 14¼° at the level of the photosphere (visual observations of sunspots).

The present paper, which confirms and extends Mr. Evershed's earlier results, is based on data derived from 200 spectra of prominences photographed last year at Pitch Hill, Surrey. For purposes of measurement, a comparison spectrum of the iron arc was used instead of the spectrum of the centre of the sun's disc as employed earlier. From a discussion of class *A* of spectrograms (those in which the lines were narrow, well-defined, or otherwise undistorted by radial motions of eruptive prominences) a first approximation of the mean shift of the spectral lines, *H* and *K*, in prominences is given as +0·0109 A., the predicted relativity shift at 28″ above the sun's surface being +0·0081 A. The outstanding difference is discussed. The paper also contains an account of Mr. Evershed's apparatus which he has installed in his underground observatory at Pitch Hill.

Research Items.

THE EARLY RACES OF AMERICA.—Dr. Etienne B. Renaud has published in the *University of Colorado Studies*, vol. 16, pt. 1, the results of an examination of two small series of skulls, one from La Plata (Colorado) and one from Cañon del Muerto (Arizona), and a comparison with other skulls from the south-west United States and from South America. The skeletal material in question is of the highest importance, not only because examples are few, but also because of its relation to the results which are now emerging from the study of the archæology of the area on scientific lines. The skulls belong to the second of the three phases in culture into which archæologists are differentiating the Indian civilisation of the south-western area of North America. These are, first, the earliest nomadic population, of which practically nothing is known, representing a late palæolithic stage; secondly, the basket-makers, representing the mesolithic culture; and, thirdly, the pueblo cliff-dwellers, a full neolithic phase, whom the Spaniards disturbed in their normal development. Of the two latter, the basket-makers were a dolichocephalic people with undeformed head, the pueblos a brachycephalic people who deformed artificially the back of the head. The two series of skulls under review belong to the basket-makers, and, apart from certain local variations, agree sufficiently in their ten characteristics here examined to warrant their being regarded as of the same race—a race which further comparison with other skeletal material reveals as a common south-western type for which as an ethnical and cultural entity the name basket-maker is suggested provisionally. The significance of this conclusion is enhanced when it is shown that this type is sufficiently cognate to warrant inclusion with the Lagoa Santo group of South America, for which Dr. Rivet and others have suggested a kinship with Melanesia and Papua—a kinship for which Dr. Rivet has argued further on linguistic grounds.

A MAGDALENIAN SITE IN THE DORDOGNE.—Excavations in La Grotte Bâtie (Crozo-Bastido) at Saint-Sosy (Lot), on the right bank of the Dordogne, are described in *L'Anthropologie*, vol. 37, Nos. 5-6, by M. Armand Viré and l'Abbé Clement Teuliere, by whom the investigations were carried out. The cave or rock shelter is situated 10 metres above a path which runs precariously along a cornice on the cliff face at an altitude of 135 metres, the height of the Dordogne at this point being 105 metres. A low wall of unknown purpose has at some time been erected at the entrance. Hence the name. The remains here described were found in the lowest of four strata, which at the centre of the cave reached a minimum depth of 1·50 metres. They include teeth and bones of reindeer which had been used as food, and a number of objects made from the antler, including a series of harpoons, mostly fragmentary or incomplete, one of them, fairly flat, resembling an Azilian type without hole. A number of bone needles were found, of which six had eyes. There were also a few piercers, but none intact. Several engravings on bone were found, of which the finest was a well-engraved horse's head showing part of the neck and chest. A shaped object with an eye on each side may be a fish or serpent. The stone implements were exclusively of flint, of varied coloration, but only rarely patinated. Scrapers and burins predominated, with scraper-burins and flakes *à dos abattu* of all sizes. One implement in particular is interesting in its resemblance to Aurignacian or early Solutrean forms. The evidence of the remains in general, but especially the harpoons, points to an Upper Magdalenian date.

OCEANIC ANGLER-FISHES.—The British Museum (Natural History) has added to its collection of post-cards two sets, each of five cards, representing some of the oceanic angler fish, mostly collected by Dr. John Schmidt, and described by Mr. C. Tate Regan (Series 1 and 2, Set M3 and M4). These are printed from beautiful drawings made by W. P. C. Tenison and are extremely interesting. The first series depicts some of the remarkable free-swimming forms, all of which are females, the males, illustrated in the second series, being parasitic on the females. These oceanic anglers are some of the most wonderful of all fishes, having the first ray of the dorsal fin modified into a lure. They live near the bottom in the deep sea where there is little or no light, the body being a uniform black colour and the lure luminous to attract the fishes on which they feed. Most of them are quite small, the female of the Atlantic *Melanocetus Johnsoni* being only 3 in. long, but it is so extremely voracious that it is sometimes found extended with fishes many times its own size. *Photocorynus spiniceps* is 2¼ in. long, the male, attached to the top of its head above the right eye, being only ¼ in. On the other hand, we have *Ceratias holboelli* trawled off Iceland, 42 in. long, the two males attached to the abdomen being a little more than 3 in. The ceratioids are unique amongst vertebrates in having the dwarf males, which actually fuse with the skin of the females, and are unlike all other animals in having the male nourished by the female's blood system.

THE POLAR FILAMENT OF THE SPORE OF NOSEMA.—K. Ohshima (*Annot. Zool. Jap.*, vol. 11, No. 3, 1927) has investigated the polar filament of the spore of *Nosema bombycis*. The extrusion of the filament was brought about by placing the spore in hydrogen peroxide solution, but the action was too rapid to permit determination of the method of extrusion, *i.e.* whether by eversion of the filament (as in the case of nematocysts) or by shooting out the filament from the extremity of the spore. The addition of 5 per cent. to 10 per cent. salt solution decreased the rate of extrusion, and the author was able to observe that the contents of the filament issue from its tip as soon as extrusion is accomplished and form a spherical droplet 3μ to 6μ in diameter. The substance of the droplet is colloidal and strongly adhesive, so that it fixes the spore to the slide. The filament is a long, fine tube of even diameter, and the author concludes that its extrusion is not due to a process of eversion. Spores examined in the digestive fluid from silkworms discharged their viscous contents from their respective filaments. The viscous material no doubt serves to fix the filament to the digestive epithelium. The digestive fluid was found to dissolve the filament in from two to five seconds. A further account is promised of the nature of the enzyme in the digestive fluid and of the nature of the proventricular fluid of the silkworm moth which causes extrusion of the polar filament but does not dissolve it. The author suggests that the viscous material discharged from the spore weakens the digestive epithelial cells and produces a condition more favourable for infection.

A NEW PARASITIC GASTROPOD.—S. Hirase describes (*Annot. Zool. Jap.*, vol. 11, No. 2, 1927) a new parasitic gastropod—*Sacculus okai*, n. g., n. sp., found in colonies imbedded in gall-like swellings of the test of tunicates in the north-western Pacific. 19 examples were found in one swelling in *Ascidia prunum* and 11 in *Boltenia ovifera*. Each of the gastropods is globular in form and about 3 mm. long and 2 mm. broad, and lies free in the lumen which communicates with the exterior by a small slit-like opening in the test. A brief account of the anatomy of Sacculus is given and the genus is placed in the Tænioglossa, though the presence of a well-developed proboscis and a bipectinate osphradium distinguish it from the other members of the sub-order. The radula is not reduced, and there is a monopectinate ctenidium with a well-developed osphradium.

NEW VARIETIES OF HOPS.—A large number of new varieties of hops have recently been raised in the Experimental Hop Garden at Wye College, and established at the East Malling Research Station. Some of the recent work, which was carried out under the auspices of the Institute of Brewing Research Scheme, is summarised by Prof. E. S. Salmon in the *Journal of the Institute of Brewing*, **33**, 488; 1927. The 112 varieties tested included new and commercial types, of which 74 cropped at the rate of at least 20 cwt. to the acre, whilst one of the former yielded 32¼ cwt. to the acre. Although in all the early, mid-season, and late classes certain new varieties had higher preservative properties than any of the commercial varieties tested, the panel of experts which judged the hops favoured certain of the latter in preference to any of the former. Comparison with the results of previous seasons, however, have shown that one new mid-season variety is gradually being regarded more favourably by the judges, and as it has high preservative properties, hopes are expressed that it will ultimately prove of value. Excellent results have been obtained in brewing trials with certain of the new varieties which have been under observation for from five to nine years. The paper also contains the scheme of manuring employed, together with notes on the diseases of the hop (cf. NATURE, **117**, 67; 1926).

SEASONAL CHANGES IN CONIFER LEAVES.—Several observers have recorded the disappearance of starch and the increase of sugars in leaves of evergreens during the winter season. The special interest of these changes lies in the possible protective action against frost. By increasing sugar concentration by 'feeding,' Lidforss succeeded in rendering glass-house plants resistant to a temperature of − 7° C., and claims that sugar prevents the precipitation of the proteins on freezing. He explains the well-known phenomenon of death from frost in spring of the leaves on the sun side of trees such as Abies, as due to earlier regeneration of starch, and the resulting lessening of the sugar content on the sun side. Prof. J. Doyle and Miss Phyllis Clinch have now taken the problem further and published (*Proc. Royal Irish Acad.*, vol. 37, B, No. 26) the results of some investigations on seasonal changes in conifer leaves with reference to enzymes and starch formation. Their observations on the autumnal disappearance and spring regeneration of starch lead them to conclude that these phenomena cannot be related to assimilation or environment changes, and that the starch-sugar equilibrium is determined in winter by protoplasmic change. They take exception to the claim of Chapman (see *Biochem. Jour.*, vol. 18, No. 6, p. 1388) that three enzymes at least—amylase, dextrinase, and maltase—must be present before starch formation can go on, and consider his experimental data insufficient to support his conclusions. Maltase seems absent from *Tsuga Albertiana*, which also lacks dextrinase and probably amylase in winter. Maltase seems also to be absent from *Pinus parviflora* in winter. The presence of amylase in winter is also doubtful in *Pinus laricio*. Yet in all these cases starch can be formed either naturally in summer or by artificially increasing the sugar concentration in winter.

TIME OF APPLICATION OF SPRAYS FOR FRUIT TREES.—Modern work on the control of pests and diseases of fruit trees lays emphasis on the importance of applying the spray fluids at a particular stage in the plant's development. A recommendation for 'spring' or 'winter' treatment is no longer considered a close enough definition. H. R. Briton-Jones and A. H. Lees, realising the inadequacy of verbal instructions for describing the necessary stages, have published a paper (*Jour. Min. Agric.*, **34**, p. 814) with numerous photographs of various types of commonly grown fruit trees in the condition when spraying will be most effective. The successive stages illustrated are roughly classified as dormant, swelling, bursting, green-flower, and pre-flowering respectively. Information concerning the various pests which may be successfully dealt with at the various stages depicted, and the most suitable type of spray for use in each case is given, and cautions are included where treatment at any stage may be useless or dangerous. Such work in achieving better standardised methods must ensure a greater degree of reliability in the employment of spray fluids, and consequently extend their use to the benefit of fruit growers.

MOVEMENTS OF THE NORTHUMBRIAN FAULT BLOCK.—The tectonic conceptions of Argand have been applied with conspicuous success to the structures of the Northumbrian fault block by Mr. H. C. Versey (*Proc. Yorkshire Geol. Soc.*, pp. 1-16, 1927). He considers the block to be a fractured *pli de fond* of Hercynian orogeny. The effect of the uplift was to develop a saddle-shaped structure in the rigid substratum, as a result of which the thin covering of carboniferous rocks was folded into small *plis de couverture*. The most northerly of these folds trends to the north-east across Teesdale and Weardale, and appears to be related genetically to the thickening of the Whin Sill. The latter is thus regarded by Mr. Versey as being locally phacolithic in its mode of emplacement. The fault block acted as a horst to the folds produced in the deposits of the Pendle trough to the south. Thus various types of virgations are exemplified in the fold-lines between the rigid areas of the Northumbrian and Midland blocks. The tectonic interpretation of the region is thought to be in good accord with the characters of the Permian rocks east and west of the block, but it should be pointed out that totally different views have recently been expressed by Mr. J. S. Turner (*Proc. Geol. Assoc.*, pp. 339-374, 1927). Both writers appeal to the composition and distribution of the Brockrams in support of their respective readings. Prof. Holmes's discovery of a pebble of Whin Sill rock in the upper Brockram near Appleby, recorded briefly in Gilligan's "Geology of Appleby," is, however, strongly in favour of the validity of Mr. Versey's conclusions.

MAGNETIC DETECTION OF MINERALS.—The economic applications of geophysical science are rapidly growing in importance, and recently led to the publication, for a time, of a *Zeitschrift für angewandte Geophysik*. An interesting account of magnetic methods of investigation of underlying minerals is contained in a lecture by Dr. L. Palazzo, published in the *Memoria d. Pont. Accad. d. Scienze—I nuovi Lincei*, Ser. 2, vol. 10, pp. 271-308. 1927. The various instruments devised for such purposes are described and illustrated, with their mode of employment. A brief account is given of the theory of local magnetic disturbance by magnetic masses below ground, and various researches on actual disturbed regions, at Kursk in Siberia, and in certain parts of Italy, are described.

The Stereoscope in Air Survey.—The need for the use of the stereoscope in plotting surveys from air photographs is now recognised and makes the publication of a simple explanation of the process most opportune. "The Stereoscopic Examination of Air Photographs," by Lieut. M. Hotine, forms No. 4 of the Professional Papers of the Air Survey Committee (London: H.M. Stationery Office. 3*s*. 6*d*.). This small volume begins with an explanation of the principles underlying stereoscopic measurement, and goes on to explain machine plotting and to describe the topographical stereoscope. A final chapter on stereoscopic training and testing should also prove valuable.

Electrical Resistance Measurements.—When an electromotive force E applied to a circuit drives a current I through it and I is proportional to R, so that in the equation $E = RI$, the resistance R of the circuit is a constant, the quotients E/I and dE/dI have the same value R, while if R is not a constant but varies with I, the second quotient has the value $R + I(dR/dI)$, and has generally been called the 'differential resistance' of the circuit. In the December issue of the *Journal of the Franklin Institute*, Mr. H. Nakamoura, of the Research Laboratory of the Tokyo Electric Company, shows that some of the methods of measurement of resistance in common use determine the ordinary resistance and some the differential resistance.
